Remotior Sensus (which is Latin for “a more remote sense”) is a Python package that allows for the processing of remote sensing images and GIS data.

**Source code:** [https://github.com/semiautomaticgit/remotior\\_sensus](https://github.com/semiautomaticgit/remotior_sensus)

**Bug reports:** [https://github.com/semiautomaticgit/remotior\\_sensus/issues](https://github.com/semiautomaticgit/remotior_sensus/issues)

## 1.1 Introduction

Remotior Sensus, developed by Luca Congedo, is a Python package that allows for the processing of remote sensing images and GIS data.

The main objective is to simplify the processing of remote sensing data through practical and integrated APIs that span from the download and preprocessing of satellite images to the postprocessing of classifications and GIS data. Basic dependencies are [NumPy](#), [SciPy](#) for calculations, and [GDAL](#) for managing spatial data.

The main features are:

- **Search and Download** of remote sensing data such as Landsat and Sentinel-2.
- **Preprocessing** of several products such as Landsat and Sentinel-2 images.
- **Processing and postprocessing** tools to perform image classification through machine learning, manage GIS data and perform spatial analyses.
- **Parallel processing** available for most processing tools.

**WARNING:** Remotior Sensus is still in early development; new tools are going to be added, tools and APIs may change, and one may encounter issues and bugs using Remotior Sensus.

### 1.1.1 Management of Raster Bands

Most tools accept raster bands as input, defined through the file path.

In addition, raster bands can be managed through a catalog of BandSets (see [bandset\\_catalog\(\)](#) (page 59)), where each BandSet is an object that includes information about single bands (from the file path to the spatial and spectral characteristics). Bands in a BandSet can be referenced by the properties thereof, such as order number or center wavelength.

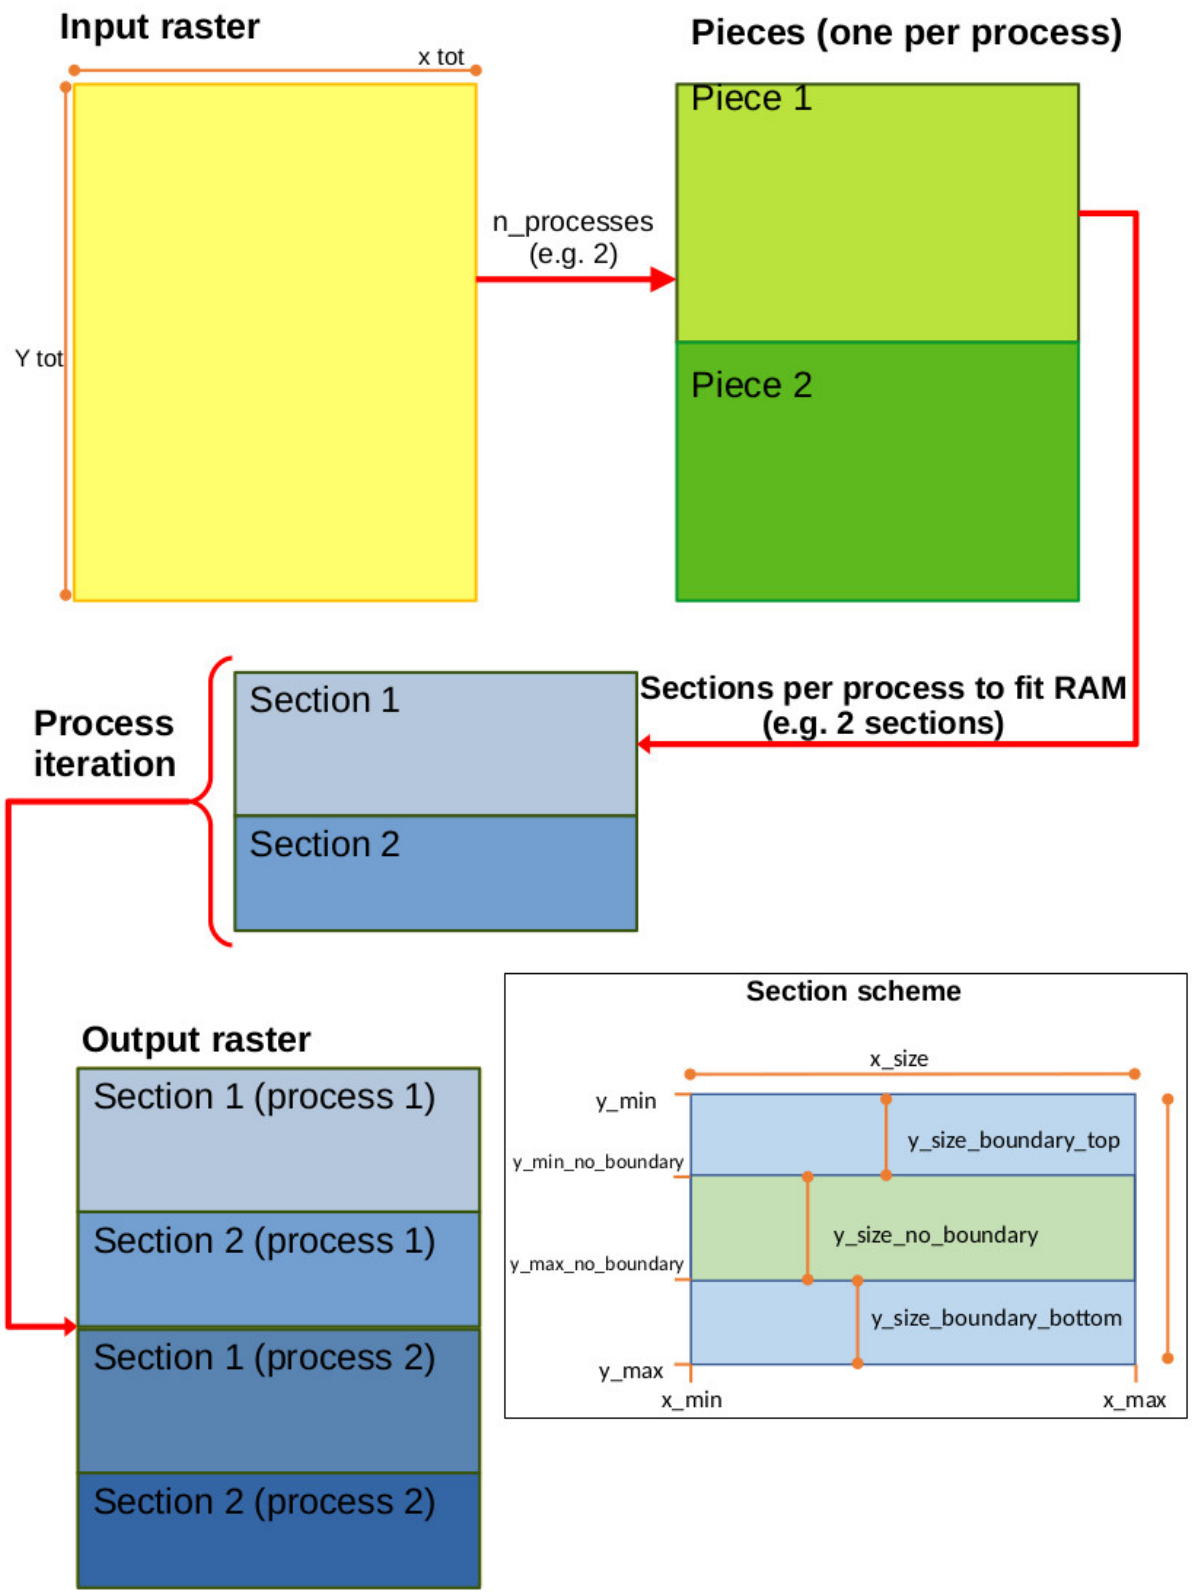

Multiple BandSets can be defined and identified by their reference number. Therefore, BandSets can be used as input for operations on multiple bands such as Principal Components Analysis, classification, mosaic, or band calculation.

In band calculations (see *band\_calc()* (page 8)) name alias of bands based on center wavelength (e.g. blue, red) can be used to simplify the structure of calculation expression.

### 1.1.2 Performance

Most tools are designed to run in parallel processes, through a simple and effective parallelization approach based on dividing the raster input in sections that are distributed to available threads, maximizing the use of available RAM. This allows even complex algorithms to run in parallel. Optionally, the output file can be a virtual raster collecting the output rasters (corresponding to the sections) written independently by parallel processes; this avoids the time required to produce a unique raster output. Most tools allow for on the fly reprojection of input data.

### 1.1.3 Machine Learning

Remotior Sensus optional dependencies are `PyTorch` and `scikit-learn`, which are integrated in the tool `band_classification()` (page 11) to allow for land cover classification through machine learning. The aim is to simplify the training process and development of the model.

### 1.1.4 Source Code

The source code of Remotior Sensus is available at [https://github.com/semiautomaticgit/remotior\\_sensus](https://github.com/semiautomaticgit/remotior_sensus) .

To report issues please visit [https://github.com/semiautomaticgit/remotior\\_sensus/issues](https://github.com/semiautomaticgit/remotior_sensus/issues) .

### License of Remotior Sensus

Remotior Sensus is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or (at your option) any later version. Remotior Sensus is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details. You should have received a copy of the GNU General Public License along with Remotior Sensus. If not, see <https://www.gnu.org/licenses/>.

From GIS to Remote Sensing

## 1.2 Installation

This section describes Remotior Sensus installation along with the required dependencies.

### 1.2.1 Dependencies

Remotior Sensus requires `GDAL`, `NumPy` and `SciPy` for most functionalities. Optionally, `scikit-learn` and `PyTorch` are required for machine learning. Python  $\geq 3.10$  is recommended.

### 1.2.2 Installation with Conda

Before installing Remotior Sensus please install the dependencies using a `Conda` environment (if you don't know `Conda` please read <https://conda-forge.org/docs>). For instance, you can use `Miniforge` to create a `Conda` environment.

```
$ conda create -c conda-forge --name environment python=3.10
Proceed ([y]/n)? y
$ conda activate environment
```

Install Remotior Sensus using `Conda` (the fundamental dependencies are also installed):

```
$ conda install -c conda-forge remotior-sensus
```

For machine learning functionalities run:

```
$ conda install -c conda-forge remotior-sensus scikit-learn pytorch
```

### 1.2.3 Installation in Linux

The suggested way to install Remotior Sensus is using *Conda* (see *Installation with Conda* (page 6)).

Depending on the system, one could install the required dependencies as:

```
$ sudo apt-get install python3-numpy python3-scipy gdal-bin
```

For Remotior Sensus package installation use *pip*:

```
$ pip install -U remotior-sensus
```

### 1.2.4 Installation in OS X

The suggested way to install Remotior Sensus is using *Conda* (see *Installation with Conda* (page 6)).

### 1.2.5 Installation in Windows

The suggested way to install Remotior Sensus is using *Conda* (see *Installation with Conda* (page 6)).

### 1.2.6 Package installation

Given that dependencies are installed, for Remotior Sensus package installation use *pip*:

```
$ pip install -U remotior-sensus
```

## 1.3 Quickstart

Following the video of the tutorial.

[https://www.youtube.com/watch?v=uv264j\\_ocIU](https://www.youtube.com/watch?v=uv264j_ocIU)

Link to the guide: <https://colab.research.google.com/gist/semiautomaticgit/0fdb7c2c5c0b3b990cf342d226b8ee43/quickstart.ipynb>

## 1.4 Basic Tutorials

The following tutorials are available.

### 1.4.1 Download Sentinel-2 Data and Calculate NDVI

Link to the guide: [https://colab.research.google.com/gist/semiautomaticgit/e20479e1cbfbf76f078bfb4f211f23fa/download\\_sentinel-2\\_data\\_and\\_calculate\\_ndvi.ipynb](https://colab.research.google.com/gist/semiautomaticgit/e20479e1cbfbf76f078bfb4f211f23fa/download_sentinel-2_data_and_calculate_ndvi.ipynb)

### 1.4.2 Random Forest Classification

Following the video of the tutorial.

<https://www.youtube.com/watch?v=Rc61ISWOgt4>

Link to the guide: [https://colab.research.google.com/gist/semiautomaticgit/5b3c6dca89b3764a69cf083cf3d0674f/random\\_forest\\_classification.ipynb](https://colab.research.google.com/gist/semiautomaticgit/5b3c6dca89b3764a69cf083cf3d0674f/random_forest_classification.ipynb)

## 1.5 Tutorials

The following tutorials are available.

## 1.5.1 Create Sentinel-2 jpg file

Link to the guide: [https://colab.research.google.com/gist/semiautomaticgit/0eb0a3e0e9794b66f162a46455b8a00d/create\\_sentinel2\\_jpg.ipynb](https://colab.research.google.com/gist/semiautomaticgit/0eb0a3e0e9794b66f162a46455b8a00d/create_sentinel2_jpg.ipynb)

## 1.6 Tools

The following are the available tools.

### 1.6.1 remotior\_sensus.tools package

#### Submodules

#### remotior\_sensus.tools.band\_calc module

Band calc.

This tool allows for mathematical calculations (pixel by pixel) between bands or single band rasters. A new raster file is created as result of calculation.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> output = rs.band_calc(
... input_raster_list=['file1.tif', 'file2.tif'], output_path='output.tif',
... expression_string='"file1 + file2"', input_name_list=['file1', 'file2']
... )
```

It is possible to iterate BandSets. BandSet iteration with structure

```
forbandsets[x1:x2]name_filter
```

or

```
forbandsets[x1,x2,x3]name_filter
```

or date iteration with structure

```
forbandsets[YYYY-MM-DD:YYYY-MM-DD]name_filter
```

or

```
forbandsets[YYYY-MM-DD, YYYY-MM-DD, YYYY-MM-DD, ...]name_filter
```

with `name_filter`: optional filter of name of first band in the BandSet.

It is possible to iterate bands in BandSet with structure

```
forbandsinbandset[x1:x2]name_filter
```

or

```
forbandsinbandset[x1,x2,x3,...]name_filter
```

or date iteration with structure

```
forbandsinbandset[YYYY-MM-DD, YYYY-MM-DD, YYYY-MM-DD, ...]name_filter
```

with `name_filter`: optional filter of name of first band in the BandSet.

`remotior_sensus.tools.band_calc.band_calc`(*expression\_string*: str, *output\_path*: None | str = None, *input\_raster\_list*: list | None = None, *input\_name\_list*: list | None = None, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *align\_raster*: None | str = None, *extent\_raster*: None | str = None, *extent\_list*: list | None = None, *extent\_intersection*: bool | None = True, *xy\_resolution\_list*: list | None = None, *input\_nodata\_as\_value*: bool | None = None, *use\_value\_as\_nodata*: None | int = None, *output\_nodata*: None | int = None, *output\_datatype*: None | str = None, *use\_scale*: None | float = None, *use\_offset*: None | float = None, *calc\_datatype*: None | str = None, *any\_nodata\_mask*: bool | None = False, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *bandset\_number*: None | int = None, *input\_bands*: [BandSet](#) (page 59) | None = None, *point\_coordinates*: list | None = None, *progress\_message*: bool | None = True, *device*=None) → [OutputManager](#) (page 96)

Performs band calculation.

Calculation is defined by an expression string using variable names that corresponds to input bands or rasters. Expression can use band alias such as “bandset1b1”, spectral band alias such as “#NIR#” for Near-Infrared and “#RED#” for Red, or expression alias such as “#NDVI#”. Multiple expression lines can be entered for serial calculation. Several iteration functions are available for band sets. NumPy functions can also be used if the output is a single band array with the same size as input raster. Input rasters can have different projection definitions, as the tool will try to reproject input rasters on the fly based on a reference raster (first input raster or `align_raster`).

#### Parameters

- **input\_raster\_list** – list of input raster paths or list of lists [path, name] ignoring `input_name_list`.
- **output\_path** – path of output file for single expression or path to a directory for multiple expression outputs.
- **expression\_string** – expression string used for calculation; multiple expressions can be entered separated by new line.
- **input\_name\_list** – list of input raster names used in expressions (if name not defined in `input_raster_list`).
- **input\_bands** – input [BandSet](#) for direct expression; in expressions, bands can be referred as “b1”, “b2”, etc.; also, spectral band alias such as “#RED#” or “#NIR#”; also “b\*” for using all the bands.
- **n\_processes** – number of threads for calculation.
- **available\_ram** – number of megabytes of RAM available to processes.
- **align\_raster** – string path of raster used for aligning output pixels and projections.
- **extent\_raster** – string path of raster used for extent reference.
- **extent\_list** – list of coordinates for defining calculation extent [left, top, right, bottom] in the same coordinates as the reference raster.
- **extent\_intersection** – if True the output extent is geometric intersection of input raster extents, if False the output extent is the maximum extent from union of input raster extents.
- **xy\_resolution\_list** – list of [x, y] pixel resolution.
- **input\_nodata\_as\_value** – if True then unmask the value of nodata pixels in calculations, if False then mask nodata pixels in calculations.

- **use\_value\_as\_nodata** – use integer value as nodata in calculation.
- **output\_nodata** – integer value used as nodata in output raster.
- **output\_datatype** – string of data type for output raster such as Float64, Float32, Int32, UInt32, Int16, UInt16, or Byte.
- **use\_scale** – float number used for scale for output.
- **use\_offset** – float number used for offset for output.
- **calc\_datatype** – data type used during calculation, which may differ from output\_datatype, such as Float64, Float32, Int32, UInt32, Int16, UInt16, or Byte.
- **any\_nodata\_mask** – if True then output nodata where any input is nodata, if False then output nodata where all the inputs are nodata, if None then do not apply nodata to output.
- **bandset\_catalog** – BandSetCatalog object for using band sets in calculations.
- **bandset\_number** – number of BandSet defined as current one.
- **point\_coordinates** – list of a point coordinates [x, y] for pixel calculations on Bandset
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

*OutputManager()* (page 96) object with

- paths = [output raster paths]

#### Examples

##### Sum of two raster files

```
>>> output_object = band_calc(
... input_raster_list=['file1.tif', 'file2.tif'], output_path='output.tif
↳',
... expression_string='"file1 + file2"', input_name_list=['file1', 'file2
↳']
... )
>>> # for instance display the output path
>>> print(output_object.paths)
['output.tif']
```

##### Calculation setting output datatype

```
>>> output_object = band_calc(
... input_raster_list=['file1.tif', 'file2.tif'], output_path='output.tif
↳',
... expression_string='"file1 + file2"', input_name_list=['file1', 'file2
↳'],
... output_datatype='Int32'
... )
```

##### Calculation setting the output extent as the maximum extent from union of input raster extents

```
>>> output_object = band_calc(
... input_raster_list=['file1.tif', 'file2.tif'], output_path='output.tif
↳',
... expression_string='"file1 + file2"', input_name_list=['file1', 'file2
↳'],
... extent_intersection=False
... )
```

## remotior\_sensus.tools.band\_classification module

Band classification.

This tool allows for the classification of remote sensing images, providing several algorithms such as Minimum Distance, Maximum Likelihood, Spectral Angle Mapping. Also, machine learning algorithms are provided through `PyTorch` (`pytorch_multi_layer_perceptron`) and `scikit-learn` (`random_forest`, `random_forest_ovr`, `support_vector_machine`, `multi_layer_perceptron`). This module includes tools for training the algorithms using Regions of Interest (ROIs) or spectral signatures.

Typical usage example:

```

>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> classification = rs.band_classification(
... input_bands=['file1.tif', 'file2.tif'], output_path='output.tif',
... algorithm_name=cfg.maximum_likelihood
... )

```

```

class remotior_sensus.tools.band_classification.Classifier(algorithm_name,
                                                         spectral_signatures,
                                                         covariance_matrices,
                                                         model_classifier,
                                                         input_normalization,
                                                         normalization_values)

```

Bases: object

Manages classifiers.

A classifier is an object which includes the required parameters to perform a classification, including the tools to perform the training.

### **algorithm\_name**

algorithm name selected form `cfg.classification_algorithms`.

### **spectral\_signatures**

a `SpectralSignaturesCatalog()` (page 109) containing spectral signatures.

### **covariance\_matrices**

dictionary of previously calculated covariance matrices (used in maximum likelihood only).

### **model\_classifier**

classifier object.

### **input\_normalization**

perform input normalization; options are `z_score` or `linear_scaling`.

### **normalization\_values**

list of normalization paramters defined for each variable [normalization expressions, mean values, standar deviation values, minimum values, maximum values].

### **framework\_name**

name of framework such as `classification_framework`, `scikit_framework`, or `pytorch_framework`.

### **classification\_function**

the actual classification function.

**function\_argument** = a dictionary including arguments for the classification function such as *model\_classifier* (page 11), *covariance\_matrices* (page 11), *normalization\_values* (page 11), *spectral\_signatures\_catalog*.

### Examples

#### Fit a classifier

```
>>> # Start a session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # create a BandSet
>>> catalog = rs.bandset_catalog()
>>> file_list = ['file1.tif', 'file2.tif', 'file3.tif']
>>> catalog.create_bandset(file_list, wavelengths=['Landsat 8'])
>>> # set a BandSet reference in signature catalog
>>> signature_catalog = rs.spectral_signatures_catalog(
>>>     bandset=catalog.get(1))
>>> # import vector in signature catalog
>>> signature_catalog.import_vector(
>>>     file_path='file.gpkg', macroclass_field='macroclass', class_
>>>     field='class',
>>>     macroclass_name_field='macroclass', class_name_field='class',
>>>     calculate_signature=True)
>>> # train a minimum distance classifier
>>> classifier = Classifier.train(
>>>     spectral_signatures=signature_catalog,
>>>     algorithm_name='minimum distance'
>>> )
```

**\_\_init\_\_**(*algorithm\_name*, *spectral\_signatures*, *covariance\_matrices*, *model\_classifier*, *input\_normalization*, *normalization\_values*)

Initializes a classifier.

A classifier is an object which includes the

#### Parameters

- **algorithm\_name** – algorithm name selected from `cfg.classification_algorithms`.
- **spectral\_signatures** – a *SpectralSignaturesCatalog()* (page 109) containing spectral signatures.
- **covariance\_matrices** – dictionary of previously calculated covariance matrices (used in maximum likelihood only).
- **model\_classifier** – classifier object.
- **input\_normalization** – perform input normalization; options are `z_score` or `linear_scaling`.
- **normalization\_values** – list of normalization parameters defined for each variable [normalization expressions, mean values, standard deviation values, minimum values, maximum values].

**classmethod load\_classifier**(*algorithm\_name=None*, *spectral\_signatures=None*, *covariance\_matrices=None*, *model\_classifier=None*, *input\_normalization=None*, *normalization\_values=None*)

Loads a classifier.

Creates a classifier from loading.

#### Parameters

- **algorithm\_name** – algorithm name selected form `cfg.classification_algorithms`.
- **spectral\_signatures** – a *SpectralSignaturesCatalog()* (page 109) containing spectral signatures.
- **covariance\_matrices** – dictionary of previously calculated covariance matrices (used in maximum likelihood only).
- **model\_classifier** – classifier object.
- **input\_normalization** – perform input normalization; options are `z_score` or `linear_scaling`.
- **normalization\_values** – list of normalization parameters defined for each variable [normalization expressions, mean values, standard deviation values, minimum values, maximum values].

#### Returns

*Classifier()* (page 11) object.

#### Examples

##### Load a classifier

```
>>> classifier = Classifier.load_classifier(
>>> algorithm_name=algorithm_name, spectral_signatures=spectral_
→signatures,
>>> covariance_matrices=covariance_matrices, model_classifier=model_
→classifier,
>>> input_normalization=input_normalization, normalization_
→values=normalization_values)
```

**run\_prediction**(*input\_raster\_list, output\_raster\_path, n\_processes: None | int = None, available\_ram: None | int = None, macroclass: bool | None = True, threshold: bool | None = False, signature\_raster: bool | None = False, classification\_confidence: bool | None = False, virtual\_raster: bool | None = None, min\_progress: int | None = 1, max\_progress: int | None = 100*) → *OutputManager* (page 96)

Runs prediction.

Performs multiprocessing classification using a trained classifier using input bands.

#### Parameters

- **input\_raster\_list** – list of paths of input rasters.
- **output\_raster\_path** – path of output file.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **macroclass** – if True, use macroclass ID from ROIs or spectral signatures; if False use class ID.
- **threshold** – if False, classification without threshold; if True, use single threshold for each signature; if float, use this value as threshold for all the signature.
- **classification\_confidence** – if True, write also additional classification confidence rasters as output.

- **signature\_raster** – if True, write additional rasters for each spectral signature as output.
- **virtual\_raster** – if True, create virtual raster output.
- **min\_progress** – minimum progress value for `Progress()` (page 101).
- **max\_progress** – maximum progress value for `Progress()` (page 101).

#### Returns

`OutputManager()` (page 96) object with

- path = [output path]

#### Examples

##### Save a trained classifier

```
>>> classifier = Classifier()
>>> # after the training
>>> prediction = classifier.run_prediction(
... input_raster_list=['file1.tif', 'file2.tif', 'file3.tif'],
... output_raster_path='file_path')
```

`save_model(output_path: str) → OutputManager` (page 96)

Saves classifier model.

Saves a classifier model to file to be loaded later.

#### Parameters

**output\_path** – path of output file.

#### Returns

`OutputManager()` (page 96) object with

- path = [output path]

#### Examples

##### Save a trained classifier

```
>>> classifier = Classifier()
>>> # after the training
>>> saved_model = classifier.save_model(output_path=output_path)
```

`classmethod train(spectral_signatures=None, algorithm_name=None, covariance_matrices=None, svc_classification_confidence=None, n_processes: int | None = None, available_ram: int | None = None, cross_validation=True, x_matrix=None, y=None, class_weight=None, input_normalization=None, normalization_values=None, find_best_estimator=False, rf_max_features=None, rf_number_trees=100, rf_min_samples_split=None, svm_c=None, svm_gamma=None, svm_kernel=None, pytorch_model=None, pytorch_optimizer=None, mlp_training_portion=None, pytorch_loss_function=None, mlp_hidden_layer_sizes=None, mlp_alpha=None, mlp_learning_rate_init=None, mlp_max_iter=None, mlp_batch_size=None, mlp_activation=None, pytorch_optimization_n_iter_no_change=None, pytorch_optimization_tol=None, pytorch_device=None, min_progress=1, max_progress=100)`

Trains a classifier.

Trains a classifier using ROIs or spectral signatures.

#### Parameters

- **spectral\_signatures** – a *SpectralSignaturesCatalog()* (page 109) containing spectral signatures.
- **algorithm\_name** – algorithm name selected from `cfg.classification_algorithms`; if None, minimum distance is used.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **cross\_validation** – if True, perform cross validation for algorithms provided through scikit-learn (`random_forest`, `random_forest_ovr`, `support_vector_machine`, `multi_layer_perceptron`).
- **x\_matrix** – optional previously saved x matrix.
- **y** – optional previously saved y matrix.
- **covariance\_matrices** – dictionary of previously calculated covariance matrices (used in maximum likelihood only).
- **svc\_classification\_confidence** – if True, write also additional classification confidence rasters as output; required information for `support_vector_machine`.
- **input\_normalization** – perform input normalization; options are `z_score` or `linear_scaling`.
- **normalization\_values** – list of normalization parameters defined for each variable [normalization expressions, mean values, standard deviation values, minimum values, maximum values].
- **class\_weight** – specific for random forest and support vector machine, if None each class has equal weight 1, if `balanced` weight is computed inversely proportional to class frequency.
- **find\_best\_estimator** – specific for scikit classifiers, if True, find automatically the best parameters and fit the model, if integer the greater the value the more are the tested combinations.
- **rf\_max\_features** – specific for random forest, if None all features are considered in node splitting, available options are `sqrt` as square root of all the features, an integer number, or a float number for a fraction of all the features.
- **rf\_number\_trees** – specific for random forest, number of trees in the forest.
- **rf\_min\_samples\_split** – specific for random forest through scikit, sets the minimum number of samples required to split an internal node; default = 2.
- **svm\_c** – specific for `support_vector_machine` through scikit, sets the regularization parameter C; default = 1.
- **svm\_gamma** – specific for `support_vector_machine` through scikit, sets the kernel coefficient; default = `scale`.
- **svm\_kernel** – specific for `support_vector_machine` through scikit, sets the kernel; default = `rbf`.
- **mlp\_training\_portion** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, the proportion of data to be used as training (default = 0.9) and the remaining part as test (default = 0.1).

- **mlp\_hidden\_layer\_sizes** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, list of values where each value defines the number of neurons in a hidden layer (e.g., `[200, 100]` for two hidden layers of 200 and 100 neurons respectively); default = `[100]`.
- **mlp\_alpha** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, weight decay (also L2 regularization term) for Adam optimizer (default = 0.0001).
- **mlp\_learning\_rate\_init** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, sets initial learning rate (default = 0.001).
- **mlp\_max\_iter** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, sets the maximum number of iterations (default = 200).
- **mlp\_batch\_size** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, sets the number of samples per batch for optimizer; if `auto`, the batch is the minimum value between 200 and the number of samples (default = `auto`).
- **mlp\_activation** – specific for `multi_layer_perceptron` and `pytorch_multi_layer_perceptron`, sets the activation function (default = `relu`).
- **pytorch\_model** – specific for `pytorch_multi_layer_perceptron`, custom `pytorch nn.Module`.
- **pytorch\_optimizer** – specific for `pytorch_multi_layer_perceptron`, custom `pytorch optimizer`.
- **pytorch\_loss\_function** – specific for `pytorch_multi_layer_perceptron`, sets a custom loss function (default = `CrossEntropyLoss`).
- **pytorch\_optimization\_n\_iter\_no\_change** – specific for `pytorch_multi_layer_perceptron`, sets the maximum number of epochs where the loss is not improving by at least the value `pytorch_optimization_tol` (default = 5).
- **pytorch\_optimization\_tol** – specific for `pytorch_multi_layer_perceptron`, sets the tolerance of optimization (default = 0.0001).
- **pytorch\_device** – specific for `pytorch_multi_layer_perceptron`, processing device `cpu` (default) or `cuda` if available.
- **min\_progress** – minimum progress value for `Progress()` (page 101).
- **max\_progress** – maximum progress value for `Progress()` (page 101).

#### Returns

`Classifier()` (page 11) object.

#### Examples

##### Load a classifier

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> signature_catalog = rs.spectral_signatures_catalog()
>>> classifier = Classifier.train(
>>> spectral_signatures=spectral_signatures,
>>> algorithm_name='minimum distance')
```

---

```

```

Performs band classification.

This tool allows for classification of raster bands using the selected algorithm.

#### Parameters

- **input\_bands** – list of input raster paths, or a BandSet number, or a previously defined BandSet.
- **output\_path** – path of output file.
- **overwrite** – if True, output overwrites existing files.
- **spectral\_signatures** – a *SpectralSignaturesCatalog()* (page 109) containing spectral signatures.
- **algorithm\_name** – algorithm name selected from `cfg.classification_algorithms`; if None, minimum distance is used.
- **bandset\_catalog** – BandSetCatalog object.
- **macroclass** – if True, use macroclass ID from ROIs or spectral signatures; if False use class ID.
- **threshold** – if False, classification without threshold; if True, use single threshold for each signature; if float, use this value as threshold for all the signature.
- **classification\_confidence** – if True, write also additional classification confidence rasters as output.
- **signature\_raster** – if True, write additional rasters for each spectral signature as output.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **cross\_validation** – if True, perform cross validation for algorithms provided through scikit-learn (`random_forest`, `random_forest_ovr`, `support_vector_machine`, `multi_layer_perceptron`).
- **load\_classifier** – path to a previously saved classifier.
- **x\_input** – optional previously saved x matrix.
- **y\_input** – optional previously saved y matrix.
- **covariance\_matrices** – dictionary of previously calculated covariance matrices (used in `maximum_likelihood`).
- **input\_normalization** – perform input normalization; options are `z_score` or `linear_scaling`.
- **only\_fit** – perform only classifier fitting.
- **save\_classifier** – save classifier to file.
- **class\_weight** – specific for random forest and support vector machine, if None each class has equal weight 1, if ‘balanced’ weight is computed inversely proportional to class frequency.
- **find\_best\_estimator** – specific for scikit classifiers, if True, find automatically the best parameters and fit the model, if integer the greater the value the more are the tested combinations.
- **rf\_max\_features** – specific for random forest, if None all features are considered in node splitting, available options are `sqrt` as square root of all the features, an integer number, or a float number for a fraction of all the features.
- **rf\_number\_trees** – specific for random forest, number of trees in the forest.

- **rf\_min\_samples\_split** – specific for random forest through scikit, sets the minimum number of samples required to split an internal node; default = 2.
- **svm\_c** – specific for support\_vector\_machine through scikit, sets the regularization parameter C; default = 1.
- **svm\_gamma** – specific for support\_vector\_machine through scikit, sets the kernel coefficient; default = scale.
- **svm\_kernel** – specific for support\_vector\_machine through scikit, sets the kernel; default = rbf.
- **mlp\_training\_portion** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, the proportion of data to be used as training (default = 0.9) and the remaining part as test (default = 0.1).
- **mlp\_hidden\_layer\_sizes** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, list of values where each value defines the number of neurons in a hidden layer (e.g., [200, 100] for two hidden layers of 200 and 100 neurons respectively); default = [100].
- **mlp\_alpha** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, weight decay (also L2 regularization term) for Adam optimizer (default = 0.0001).
- **mlp\_learning\_rate\_init** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, sets initial learning rate (default = 0.001).
- **mlp\_max\_iter** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, sets the maximum number of iterations (default = 200).
- **mlp\_batch\_size** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, sets the number of samples per batch for optimizer; if auto, the batch is the minimum value between 200 and the number of samples (default = auto).
- **mlp\_activation** – specific for multi\_layer\_perceptron and pytorch\_multi\_layer\_perceptron, sets the activation function (default = relu).
- **pytorch\_model** – specific for pytorch\_multi\_layer\_perceptron, custom pytorch nn.Module.
- **pytorch\_optimizer** – specific for pytorch\_multi\_layer\_perceptron, custom pytorch optimizer.
- **pytorch\_loss\_function** – specific for pytorch\_multi\_layer\_perceptron, sets a custom loss function (default CrossEntropyLoss).
- **pytorch\_optimization\_n\_iter\_no\_change** – specific for pytorch\_multi\_layer\_perceptron, sets the maximum number of epochs where the loss is not improving by at least the value pytorch\_optimization\_tol (default = 5).
- **pytorch\_optimization\_tol** – specific for pytorch\_multi\_layer\_perceptron, sets the tolerance of optimization (default = 0.0001).
- **pytorch\_device** – specific for pytorch\_multi\_layer\_perceptron, processing device cpu (default) or cuda if available.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

## Returns

If `only_fit` is True returns `OutputManager()` (page 96) object with

- extra = { 'classifier': classifier, 'model\_path': output model path }

If only\_fit is False returns *OutputManager()* (page 96) object with

- path = classification path
- extra = {'model\_path': output model path}

### remotior\_sensus.tools.band\_clip module

Band clip.

This tool allows for clipping the bands of a BandSet.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # box coordinate list
>>> extent_list = [230250, 4674510, 230320, 4674440]
>>> # start the process
>>> clip = rs.band_clip(input_bands=['path_1', 'path_2'],
... output_path='output_path', extent_list=extent_list)
```

`remotior_sensus.tools.band_clip.band_clip`(*input\_bands*: list | int | *BandSet* (page 59), *output\_path*: str | list | None = None, *vector\_path*: str | None = "", *vector\_field*: None | str = None, *overwrite*: bool | None = False, *prefix*: str | None = "", *extent\_list*: list | None = None, *multiple\_resolution*: bool | None = True, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: *BandSetCatalog* (page 70) | None = None, *virtual\_output*: bool | None = None, *progress\_message*: bool | None = True) → *OutputManager* (page 96)

Perform band clip.

This tool allows for clipping the bands of a BandSet based on a vector or list of boundary coordinates left top right bottom.

#### Parameters

- **input\_bands** – input of type BandSet or list of paths or integer number of BandSet.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **vector\_path** – path of vector used to clip.
- **vector\_field** – vector field name used to clip for every unique ID.
- **virtual\_output** – if True (and output\_path is directory), save output as virtual raster of multiprocessing parts
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number

- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

Object `OutputManager()` (page 96) with

- paths = output list

### Examples

#### Clip using vector

```
>>> # start the process
>>> clip = band_clip(input_bands=['path_1', 'path_2'],
... output_path='output_path', vector_path='vector_path',
... prefix='clip_')
```

## remotior\_sensus.tools.band\_clustering module

Band clustering.

This tool allows for the automatic clustering of a BandSet or a list of files.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create a BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> # start the process
>>> output = rs.band_clustering(
... input_bands=catalog.get_bandset(1), output_raster_path='output.tif',
... algorithm_name='minimum distance', class_number=10,
... seed_signatures='random pixel'
... )
```

`remotior_sensus.tools.band_clustering.band_clustering`(*input\_bands*: list | int | BandSet (page 59), *output\_raster\_path*: str, *algorithm\_name*: str, *class\_number*: int, *seed\_signatures*: str | SpectralSignaturesCatalog (page 109) | None = None, *threshold*: None | float = None, *max\_iter*: None | int = None, *overwrite*: bool | None = False, *nodata\_value*: None | int = None, *extent\_list*: list | None = None, *n\_processes*: None | int = None, *available\_ram*: int | None = None, *bandset\_catalog*: BandSetCatalog (page 70) | None = None, *progress\_message*: bool | None = True) → `OutputManager` (page 96)

Calculation of Band Clustering.

This tool allows for the calculation of Band Clustering. A classification raster file is created. In addition, the spectral signatures of the final iteration are saved as .scpx file.

## Parameters

- **input\_bands** – input of type BandSet or list of paths or integer number of BandSet.
- **output\_raster\_path** – path of output file.
- **algorithm\_name** – algorithm name selected from `cfg.classification_algorithms` between minimum distance and spectral angle mapping.
- **class\_number** – the output number of classes (default = 10).
- **seed\_signatures** – the type of seed signatures (random pixel or band mean) or a [SpectralSignaturesCatalog\(\)](#) (page 109) containing spectral signatures, or path of spectral signature file.
- **threshold** – if None, classification without threshold; if float, use this value as threshold for all the signatures.
- **max\_iter** – sets the maximum number of iterations (default = 10).
- **overwrite** – if True, output overwrites existing files.
- **nodata\_value** – value to be considered as nodata.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

## Returns

Object [OutputManager\(\)](#) (page 96) with

- path = [output path]
- extra = {'signature\_path': output spectral signature .scpx file path}

### Examples

#### Perform the clustering on a list of files

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # input file list
>>> file_list_2 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> # start the process
>>> output = rs.band_clustering(
... input_bands=file_list_2, output_raster_path='output.tif',
... algorithm_name='minimum distance', class_number=10,
... seed_signatures='band mean'
... )
```

## remotior\_sensus.tools.band\_combination module

Band combination.

This tool is intended for combining classifications in order to get a raster where each value corresponds to a combination of class values. A unique value is assigned to each combination of values. The output is a raster made of

unique values corresponding to combinations of values. An output text file describes the correspondence between unique values and combinations, as well as the statistics of each combination.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> combination = rs.band_combination(input_bands=['path_1', 'path_2'],
... output_path='output_path')
```

`remotior_sensus.tools.band_combination.band_combination`(*input\_bands*: list | int | [BandSet](#) (page 59), *output\_path*: None | str = None, *nodata\_value*: None | int = None, *no\_raster\_output*: bool | None = False, *overwrite*: bool | None = False, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *extent\_list*: list | None = None, *column\_name\_list*: list | None = None, *output\_table*: bool | None = True, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Calculation of band combination.

This tool allows for the combination of rasters or bands loaded in a `BandSet`. This tool is intended for combining classifications in order to get a raster where each value corresponds to a combination of class values. Input raster values must be integer type. The output is a combination raster and a text file reporting the statistics of each combination.

#### Parameters

- **input\_bands** – list of paths of input rasters, or number of `BandSet`, or `BandSet` object.
- **output\_path** – path of the output raster.
- **no\_raster\_output** – if True, no output raster is written to file.
- **overwrite** – if True, output overwrites existing files.
- **nodata\_value** – input value to be considered as nodata.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – `BandSetCatalog` object required if `input_bands` is a `BandSet` number.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **column\_name\_list** – list of strings corresponding to input bands used as column names in output table, if None then column names are extracted for input band names.
- **output\_table** – if True then calculate output table; if False then calculate only array of combinations and sum.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

If `output_table` is True returns the [OutputManager\(\)](#) (page 96) object with

- paths = [output raster path, output table path]

If `output_table` is `False` returns the `OutputManager()` (page 96) object with

- paths = [virtual raster path]
- extra = { 'combinations': array of combinations, 'sums': array of the sums of values }

### Examples

#### Combination using two rasters having paths `path_1` and `path_2`

```
>>> combination = band_combination(input_bands=['path_1', 'path_2'],
↳ output_path='output_path')
```

The combination raster and the table are finally created; the paths can be retrieved from the output that is an `OutputManager()` (page 96) object

```
>>> raster_path, table_path = combination.paths
>>> print(raster_path)
output_path
```

#### Combination using a virtual raster as output file

```
>>> combination = band_combination(input_bands=['path_1', 'path_2'],
↳ output_path='output_path.vrt')
>>> raster_path, table_path = combination.paths
>>> print(raster_path)
output_path.vrt
```

#### Using input `BandSet` number

```
>>> catalog = BandSetCatalog()
>>> combination = band_combination(input_bands=1, output_path='output_path
↳ ', bandset_catalog=catalog)
```

#### Using input `BandSet`

```
>>> catalog = BandSetCatalog()
>>> combination = band_combination(input_bands=catalog.get_bandset(1),
↳ output_path='output_path')
```

## remotior\_sensus.tools.band\_dilation module

Band dilation.

This tool allows for the spatial dilation, through a moving window, of band pixels selected by values.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> dilation = rs.band_dilation(input_bands=['file1.tif', 'file2.tif'],
... value_list=[1], size=3, output_path='directory_path',
... circular_structure=True, prefix='dilation_')
```

`remotior_sensus.tools.band_dilation.band_dilation`(*input\_bands*: list | int | [BandSet](#) (page 59),  
*value\_list*: list, *size*: int, *output\_path*: str | list | None = None, *overwrite*: bool | None = False,  
*circular\_structure*: bool | None = None, *prefix*: str | None = "", *extent\_list*: list | None = None,  
*multiple\_resolution*: bool | None = True, *n\_processes*: None | int = None,  
*available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None,  
*virtual\_output*: bool | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Perform dilation of band pixels.

This tool performs the dilation of pixels identified by a list of values. A new raster is created for each input band.

### Parameters

- **input\_bands** – input of type `BandSet` or list of paths or integer number of `BandSet`.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **value\_list** – list of values for dilation.
- **size** – size of dilation in pixels.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts
- **circular\_structure** – if True, use circular structure; if False, square structure.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type `BandSetCatalog` for `BandSet` number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

Object `OutputManager()` (page 96) with

- `paths` = output list

### Examples

Perform the dilation of size 5 for value 1 and 2

```
>>> dilation = band_dilation(input_bands=['path_1', 'path_2'],value_
↳list=[1, 2],size=5,output_path='directory_path',circular_
↳structure=True)
```

## remotior\_sensus.tools.band\_erosion module

Band erosion.

This tool allows for the spatial erosion, through a moving window, of band pixels selected by values.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> erosion = rs.band_erosion(input_bands=['file1.tif', 'file2.tif'],
... value_list=[1], size=1, output_path='directory_path',
... circular_structure=True, prefix='erosion_')
```

```
remotior_sensus.tools.band_erosion.band_erosion(input_bands: list | int | BandSet (page 59),
value_list: list, size: int, output_path: str | list |
None = None, overwrite: bool | None = False,
circular_structure: bool | None = None, prefix:
str | None = "", extent_list: list | None = None,
multiple_resolution: bool | None = True,
n_processes: None | int = None, available_ram:
None | int = None, bandset_catalog:
BandSetCatalog (page 70) | None = None,
virtual_output: bool | None = None,
progress_message: bool | None = True) →
OutputManager (page 96)
```

Perform erosion of band pixels.

This tool performs the erosion of pixels identified by a list of values. A new raster is created for each input band.

### Parameters

- **input\_bands** – input of type BandSet or list of paths or integer number of BandSet.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **value\_list** – list of values for dilation.
- **size** – size of dilation in pixels.
- **virtual\_output** – if True (and output\_path is directory), save output as virtual raster of multiprocessing parts.
- **circular\_structure** – if True, use circular structure; if False, square structure.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

Object `OutputManager()` (page 96) with

- `paths` = output list

#### Examples

Perform the erosion of size 1 for value 1 and 2

```
>>> erosion = band_erosion(
... input_bands=['path_1', 'path_2'], value_list=[1, 2], size=1,
... output_path='directory_path', circular_structure=True
... )
```

### remotior\_sensus.tools.band\_mask module

Band mask.

This tool allows for masking bands using a vector or raster mask.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> rs.band_mask(input_bands=['path_1', 'path_2'],
... input_mask='mask_path', mask_values=[1, 2]
... output_path='output_path')
```

`remotior_sensus.tools.band_mask.band_mask`(*input\_bands*: list | int | [BandSet](#) (page 59), *input\_mask*: str | None = None, *mask\_values*: list | None = None, *output\_path*: None | str = None, *overwrite*: bool | None = False, *buffer*: None | int = None, *nodata\_value*: None | int = None, *virtual\_output*: bool | None = None, *compress*=None, *compress\_format*=None, *prefix*: str | None = "", *extent\_list*: list | None = None, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Performs band mask.

This tool allows for masking bands using a vector or raster mask.

#### Parameters

- **input\_bands** – reference\_raster of type `BandSet` or list of paths or integer number of `BandSet`.
- **input\_mask** – string path of raster or vector used for masking.
- **mask\_values** – list of values in the mask to be used for masking.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **buffer** – optional buffer size, in number of pixels, to expand the mask.
- **nodata\_value** – value to be used as nodata in the output.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts.

- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **compress** – if True, compress output.
- **compress\_format** – format of compressions such as LZW or DEFLATE.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object `OutputManager()` (page 96) with

- `paths` = output list

#### Examples

##### Perform the band resample

```
>>> band_mask(input_bands=['path_1', 'path_2'],
... input_mask='mask_path', mask_values=[1, 2],
... output_path='output_path')
```

#### remotior\_sensus.tools.band\_neighbor\_pixels module

Band neighbor pixels.

This tool allows for the calculation of a function over neighbor pixels defined by size (i.e. number of pixels) or a structure.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> neighbor = rs.band_neighbor_pixels(
... input_bands=['file1.tif', 'file2.tif'],
... size=1, output_path='directory_path', stat_name='Mean',
... circular_structure=True, prefix='neighbor_'
... )
```

`remotior_sensus.tools.band_neighbor_pixels.band_neighbor_pixels`(*input\_bands*: list | int | [BandSet](#) (page 59), *size*: int, *output\_path*: None | str = None, *overwrite*: bool | None = False, *stat\_name*: str | None = None, *structure*: any | None = None, *circular\_structure*: bool | None = True, *stat\_percentile*: None | int | str = None, *output\_data\_type*: None | str = None, *virtual\_output*: bool | None = None, *prefix*: str | None = "", *extent\_list*: list | None = None, *multiple\_resolution*: bool | None = True, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Performs band neighbor pixels.

This tool calculates a function over neighbor pixels defined by size (i.e. number of pixels) or structure. A new raster is created for each input band, where each pixel is the result of the calculation of the function over the neighbor pixels (e.g. the mean of the pixel values of a 3x3 window around the pixel). Available functions are:

- Count
- Max
- Mean
- Median
- Min
- Percentile
- StandardDeviation
- Sum

#### Parameters

- **input\_bands** – input of type `BandSet` or list of paths or integer number of `BandSet`.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **size** – size of dilation in pixels.
- **structure** – optional path to csv file of structures, if None then the structure is created from size.
- **circular\_structure** – if True use circular structure.
- **stat\_name** – statistic name as in `configurations.statistics_list`.

- **stat\_percentile** – integer value for percentile parameter.
- **output\_data\_type** – optional raster output data type, if None the data type is the same as input raster.
- **virtual\_output** – if True (and output\_path is directory), save output as virtual raster of multiprocessing parts.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object [OutputManager\(\)](#) (page 96) with

- paths = output list

#### Examples

Perform the band neighbor of size 10 pixels with the function Sum

```
>>> neighbor = band_neighbor_pixels(
... input_bands=['file1.tif', 'file2.tif'], size=10,
... output_path='directory_path', stat_name='Sum',
... circular_structure=True
... )
```

#### remotior\_sensus.tools.band\_pca module

Band PCA.

This tool allows for the calculation of Principal Components Analysis on input bands, producing rasters corresponding to the principal components.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create a BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> # start the process
>>> output = rs.band_pca(input_bands=catalog.get_bandset(1),
... output_path='directory_path')
```

`remotior_sensus.tools.band_pca.band_pca`(*input\_bands*: list | int | [BandSet](#) (page 59), *normalize*: bool | None = False, *output\_path*: str | list | None = None, *overwrite*: bool | None = False, *nodata\_value*: None | int = None, *extent\_list*: list | None = None, *n\_processes*: None | int = None, *available\_ram*: int | None = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *number\_components*: None | int = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Calculation of Principal Components Analysis.

This tool allows for the calculation of Principal Components Analysis of raster bands obtaining the principal components. A new raster file is created for each component. In addition, a table containing the Principal Components statistics is created.

#### Parameters

- **input\_bands** – input of type [BandSet](#) or list of paths or integer number of [BandSet](#).
- **normalize** – if True, normalize input bands as .
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **nodata\_value** – value to be considered as nodata.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type [BandSetCatalog](#) for [BandSet](#) number.
- **number\_components** – defines the maximum number of components calculated.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object [OutputManager\(\)](#) (page 96) with

- paths = output list
- extra = {'table': table path string}

#### Examples

##### Perform the PCA on the first BandSet

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create a BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> # start the process
>>> pca = rs.band_pca(input_bands=catalog.get_bandset(1), output_path=
↳ 'directory_path')
```

## remotior\_sensus.tools.band\_resample module

Band resample.

This tool allows for resampling and reprojecting bands.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> rs.band_resample(input_bands=['path_1', 'path_2'],
... output_path='output_path')
```

```
remotior_sensus.tools.band_resample.band_resample(input_bands: list | int | BandSet \(page 59\),
output_path: None | str = None, epsg_code:
None | str = None, align_raster: str | BandSet
\(page 59\) | int | None = None, overwrite: bool |
None = False, resampling: None | str = None,
nodata_value: None | int = None,
x_y_resolution: list | int | None = None,
resample_pixel_factor: None | float = None,
output_data_type: None | str = None,
same_extent: bool | None = False,
virtual_output: bool | None = None,
compress=None, compress_format=None,
prefix: str | None = "", extent_list: list | None =
None, multiple_resolution: bool | None = True,
n_processes: None | int = None,
available_ram: None | int = None,
bandset_catalog: BandSetCatalog \(page 70\) |
None = None, progress_message: bool | None
= True) → OutputManager \(page 96\)
```

Performs band resample and reprojection.

This tool performs the resampling and reprojection of raster bands. Available resampling methods are:

- nearest\_neighbour
- average
- sum
- maximum
- minimum
- mode
- median
- first\_quartile
- third\_quartile

### Parameters

- **input\_bands** – input of type `BandSet` or list of paths or integer number of `BandSet`.
- **output\_path** – string of output path directory or list of paths.
- **epsg\_code** – optional EPSG code for output.
- **align\_raster** – string path of raster used for aligning output pixels and projections.

- **overwrite** – if True, output overwrites existing files.
- **resampling** – method of resample such as nearest\_neighbour (default), average, sum, maximum, minimum, mode, median, first\_quartile, third\_quartile.
- **nodata\_value** – value to be considered as nodata.
- **x\_y\_resolution** – integer pixel size of output raster or pixel size as list of x, y.
- **resample\_pixel\_factor** – define output resolution by multiplying original pixel size to this value.
- **output\_data\_type** – optional raster output data type, if None the data type is the same as input raster.
- **same\_extent** – if True, output extent is the same as align\_raster.
- **virtual\_output** – if True (and output\_path is directory), save output as virtual raster of multiprocessing parts.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **compress** – if True, compress output.
- **compress\_format** – format of compressions such as LZW or DEFLATE.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type BandSetCatalog for BandSet number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object *OutputManager()* (page 96) with

- paths = output list

#### Examples

##### Perform the band resample

```
>>> band_resample(
...   input_bands=['path_1', 'path_2'], output_path='output_path',
...   resampling='mode', resample_pixel_factor=2
... )
```

#### remotior\_sensus.tools.band\_sieve module

Band sieve.

This tool allows for performing the sieve of raster bands removing patches having size lower than a threshold (i.e. number of pixels).

Typical usage example:

```

>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> sieve = rs.band_sieve(
...   input_bands=['file1.tif', 'file2.tif'], size=2,
...   output_path='directory_path', connected=False, prefix='sieve_'
... )

```

`remotior_sensus.tools.band_sieve.band_sieve`(*input\_bands*: list | int | [BandSet](#) (page 59), *size*: int, *output\_path*: str | list | None = None, *connected*: bool | None = None, *overwrite*: bool | None = False, *prefix*: str | None = "", *extent\_list*: list | None = None, *multiple\_resolution*: bool | None = True, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *virtual\_output*: bool | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Perform band sieve.

This tool allows for performing the sieve of raster bands removing patches having size lower than a threshold (i.e. number of pixels).

#### Parameters

- **input\_bands** – input of type `BandSet` or list of paths or integer number of `BandSet`.
- **output\_path** – string of output path directory or list of paths.
- **overwrite** – if True, output overwrites existing files.
- **size** – size of dilation in pixels.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts
- **connected** – if True, consider 8 pixel connection; if False, consider 4 pixel connection.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **multiple\_resolution** – if True, keep the original resolution of individual raster; if False, use the resolution of the first raster for all the bands.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – optional type `BandSetCatalog` for `BandSet` number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object [OutputManager\(\)](#) (page 96) with

- `paths` = output list

#### Examples

Perform the sieve of size 3 with connected pixel (8 connection)

```
>>> sieve = band_sieve(
... input_bands=['file1.tif', 'file2.tif'], size=3,
... output_path='directory_path', connected=True, prefix='sieve_'
... )
```

### remotior\_sensus.tools.band\_spectral\_distance module

Band spectral distance.

This tool allows for calculating the spectral distance pixel by pixel between two BandSets.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create three BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> file_list_2 = ['file2_b1.tif', 'file2_b2.tif', 'file2_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> catalog.create_bandset(file_list_2, bandset_number=2)
>>> distance = rs.band_spectral_distance(
... input_bandsets=[catalog.get(1), catalog.get(2)], output_path='output_path',
... )
```

`remotior_sensus.tools.band_spectral_distance.band_spectral_distance`(*input\_bandsets*: list, *output\_path*: None | str = None, *algorithm\_name*: None | str = None, *nodata\_value*: None | int = None, *threshold*: None | float = None, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *virtual\_output*: bool | None = False, *overwrite*: bool | None = False, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Band spectral distance.

This tool allows for calculating the spectral distance pixel by pixel between two BandSets, which can be useful for change detection. A new raster is created where pixel values represent the spectral distance between pixels of input BandSets. Optionally, a threshold value can be defined to create a binary raster where pixel value is 1 if distance > threshold or 0 otherwise.

#### Parameters

- **input\_bandsets** – list of number of BandSets, or BandSet objects.

- **output\_path** – string of output path directory.
- **algorithm\_name** – algorithm name selected from `cfg.classification_algorithms`.
- **nodata\_value** – value to be considered as nodata.
- **threshold** – threshold value to create a binary raster if distance > threshold.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts.
- **overwrite** – if True, output overwrites existing files.
- **bandset\_catalog** – optional type `BandSetCatalog` for `BandSet` number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

Object `OutputManager()` (page 96) with

- `path` = output path

### Examples

Perform the spectral distance of two `BandSets` using threshold

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create three BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> file_list_2 = ['file2_b1.tif', 'file2_b2.tif', 'file2_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> catalog.create_bandset(file_list_2, bandset_number=2)
>>> # start the process
>>> distance = rs.band_spectral_distance(
... input_bandsets=[1, 2], output_path='output_path',
... threshold=1000, bandset_catalog=catalog
... )
```

### remotior\_sensus.tools.band\_stack module

Band stack.

This tool allows for stacking single bands in a multiband raster.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> stack = rs.band_stack(input_bands=['path_1', 'path_2'],
... output_path='output_path')
```

`remotior_sensus.tools.band_stack.band_stack`(*input\_bands*: list | int | [BandSet](#) (page 59),  
*output\_path*: None | str = None, *overwrite*: bool | None = False, *extent\_list*: list | None = None,  
*bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *n\_processes*: None | int = None, *virtual\_output*:  
bool | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Stack single bands.

This tool allows for stacking single bands in a multiband raster.

#### Parameters

- **input\_bands** – list of paths of input rasters, or number of [BandSet](#), or [BandSet](#) object.
- **output\_path** – string of output path.
- **overwrite** – if True, output overwrites existing files.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **bandset\_catalog** – [BandSetCatalog](#) object required if `input_bands` is a [BandSet](#) number.
- **n\_processes** – number of parallel processes.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object [OutputManager\(\)](#) (page 96) with

- `path` = output path

#### Examples

##### Perform band stack

```
>>> stack = band_stack(input_bands=['path_1', 'path_2'],
... output_path='output_path')
```

## remotior\_sensus.tools.cross\_classification module

Cros classification.

This tool performs the cross classification which is similar to band combination, but it is executed between two files only. The reference file can also be of vector type. A unique value is assigned to each combination of values. The output is a raster made of unique values corresponding to combinations of values. An output text file describes the correspondance between unique values and combinations, as well as the statistics of each combination, with the option to calculate an error matrix or linear regression.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> cross = rs.cross_classification(
... classification_path='file1.tif', reference_path='file2.tif',
```

(continues on next page)

(continued from previous page)

```
... output_path='output.tif'
... )
```

```
remotior_sensus.tools.cross_classification.cross_classification(classification_path: str,
                                                                reference_path: str,
                                                                output_path: None | str =
                                                                None, overwrite: bool | None
                                                                = False, vector_field: None |
                                                                str = None, nodata_value:
                                                                None | int = None,
                                                                cross_matrix: bool | None =
                                                                False, regression_raster:
                                                                bool | None = False,
                                                                error_matrix: bool | None =
                                                                False, extent_list: list | None
                                                                = None, n_processes: None |
                                                                int = None, available_ram:
                                                                None | int = None,
                                                                progress_message: bool |
                                                                None = True) →
                                                                OutputManager (page 96)
```

Calculation of cross classification.

This tool allows for the cross classification of two files (a classification raster and a reference vector or raster) in order to get a raster where each value corresponds to a combination of class values. Input raster values must be integer type. The output is a cross raster and, depending on the parameters, a text file reporting the statistics of each combination, error matrix, or linear regression statistics.

### Parameters

- **classification\_path** – path of raster used as classification input.
- **reference\_path** – path of the vector or raster file used as reference input.
- **vector\_field** – in case of vector reference, the name of the field used as reference value.
- **output\_path** – path of the output raster.
- **overwrite** – if True, output overwrites existing files.
- **nodata\_value** – value to be considered as nodata.
- **cross\_matrix** – if True then calculate the cross matrix.
- **regression\_raster** – if True then calculate linear regression statistics.
- **error\_matrix** – if True then calculate error matrix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

Object *OutputManager*() (page 96) with

- paths = [output raster path, output table path]

**Examples****Perform the cross classification between two files**

```
>>> cross = cross_classification(
... classification_path='file1.tif', reference_path='file2.tif',
... output_path='output.tif'
... )
```

**Perform the cross classification between two files and calculate the error matrix**

```
>>> cross = cross_classification(
... classification_path='file1.tif', reference_path='file2.tif',
... output_path='output.tif', error_matrix=True
... )
```

**remotior\_sensus.tools.download\_products module**

Download products.

This tool allows for downloading products such as Landsat and Sentinel-2 datasets.

```
remotior_sensus.tools.download_products.delete_copernicus_token(access_token, session_state,
                                                                proxy_host=None,
                                                                proxy_port=None,
                                                                proxy_user=None,
                                                                proxy_password=None)
```

```
remotior_sensus.tools.download_products.download(product_table, output_path, exporter=False,
                                                band_list=None, virtual_download=False,
                                                extent_coordinate_list=None, proxy_host=None,
                                                proxy_port=None, proxy_user=None,
                                                proxy_password=None,
                                                authentication_uri=None, nasa_user=None,
                                                nasa_password=None, copernicus_user=None,
                                                copernicus_password=None,
                                                progress_message=True, ignore_errors=False)
→ OutputManager (page 96)
```

Download products.

This tool downloads product. Downloads Sentinel-2 images using the following Google service: <https://storage.googleapis.com/gcp-public-data-sentinel-2> or <https://catalogue.dataspace.copernicus.eu> if `copernicus_user` and `copernicus_password` are provided.

Downloads HLS images from: [https://cmr.earthdata.nasa.gov/search/site/search\\_api\\_docs.html](https://cmr.earthdata.nasa.gov/search/site/search_api_docs.html).

**Parameters**

- **product\_table** – product table object.
- **output\_path** – string of output path.
- **exporter** – if True, export download urls.
- **band\_list** – list of band numbers to be downloaded.
- **virtual\_download** – if True create a virtual raster of the linked image.
- **extent\_coordinate\_list** – list of coordinates for defining a subset region [left, top, right, bottom] .
- **proxy\_host** – proxy host.

- **proxy\_port** – proxy port.
- **proxy\_user** – proxy user.
- **proxy\_password** – proxy password.
- **authentication\_uri** – authentication uri.
- **nasa\_user** – user for NASA authentication.
- **nasa\_password** – password for NASA authentication.
- **copernicus\_user** – user for Copernicus authentication.
- **copernicus\_password** – password for Copernicus authentication.
- **progress\_message** – progress message.
- **ignore\_errors** – if True, ignore download errors and continue with the next product download.

### Returns

object *OutputManager*() (page 96) with

- paths = output file list
- extra={'directory\_paths': list of output directory paths}

`remotior_sensus.tools.download_products.export_product_table_as_xml(product_table,  
output_path=None)`

Exports product table as xml.

Exports a product table and attributes.

`remotior_sensus.tools.download_products.get_copernicus_token(user, password,  
authentication_uri=None,  
proxy_host=None,  
proxy_port=None,  
proxy_user=None,  
proxy_password=None)`

`remotior_sensus.tools.download_products.import_as_xml(xml_path)`

Imports a product table as xml.

Imports a product table and attributes.

`remotior_sensus.tools.download_products.product_names()` → list

Prints the products that can be searched and returns the list.

`remotior_sensus.tools.download_products.query_aster_l1t_mpc(date_from, date_to,  
max_cloud_cover=100,  
result_number=50,  
name_filter=None,  
coordinate_list=None,  
progress_message=True,  
proxy_host=None,  
proxy_port=None,  
proxy_user=None,  
proxy_password=None) →  
OutputManager (page 96)`

Perform the query of ASTER from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

### Parameters

- **date\_from** – date defining the starting period of the query

- `date_to`
- `max_cloud_cover`
- `result_number`
- `name_filter`
- `coordinate_list`
- `progress_message`
- `proxy_host`
- `proxy_port`
- `proxy_user`
- `proxy_password`

**Returns**

object `OutputManger`

```
remotior_sensus.tools.download_products.query_cop_dem_glo_30_mpc(date_from, date_to,  
                                                                max_cloud_cover=100,  
                                                                result_number=50,  
                                                                name_filter=None,  
                                                                coordinate_list=None,  
                                                                progress_message=True,  
                                                                proxy_host=None,  
                                                                proxy_port=None,  
                                                                proxy_user=None,  
                                                                proxy_password=None) →  
                                                                OutputManager (page 96)
```

Perform the query of MODIS temperature from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

**Parameters**

- `date_from` – date defining the starting period of the query
- `date_to`
- `max_cloud_cover`
- `result_number`
- `name_filter`
- `coordinate_list`
- `progress_message`
- `proxy_host`
- `proxy_port`
- `proxy_user`
- `proxy_password`

**Returns**

object `OutputManger`

`remotior_sensus.tools.download_products.query_landsat_mpc`(*date\_from*, *date\_to*,  
*max\_cloud\_cover*=100,  
*result\_number*=50,  
*name\_filter*=None,  
*coordinate\_list*=None,  
*progress\_message*=True,  
*proxy\_host*=None,  
*proxy\_port*=None,  
*proxy\_user*=None,  
*proxy\_password*=None) →  
*OutputManager* (page 96)

Perform the query of Landsat from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

### Parameters

- **date\_from** – date defining the starting period of the query
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**
- **coordinate\_list**
- **progress\_message**
- **proxy\_host**
- **proxy\_port**
- **proxy\_user**
- **proxy\_password**

### Returns

object *OutputManger*

`remotior_sensus.tools.download_products.query_modis_09q1_mpc`(*date\_from*, *date\_to*,  
*max\_cloud\_cover*=100,  
*result\_number*=50,  
*name\_filter*=None,  
*coordinate\_list*=None,  
*progress\_message*=True,  
*proxy\_host*=None,  
*proxy\_port*=None,  
*proxy\_user*=None,  
*proxy\_password*=None) →  
*OutputManager* (page 96)

Perform the query of MODIS from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

### Parameters

- **date\_from** – date defining the starting period of the query
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**

- `coordinate_list`
- `progress_message`
- `proxy_host`
- `proxy_port`
- `proxy_user`
- `proxy_password`

**Returns**

object `OutputManger`

`remotior_sensus.tools.download_products.query_modis_11a2_mpc`(*date\_from*, *date\_to*,  
*max\_cloud\_cover=100*,  
*result\_number=50*,  
*name\_filter=None*,  
*coordinate\_list=None*,  
*progress\_message=True*,  
*proxy\_host=None*,  
*proxy\_port=None*,  
*proxy\_user=None*,  
*proxy\_password=None*) →  
*OutputManager* (page 96)

Perform the query of MODIS temperature from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

**Parameters**

- `date_from` – date defining the starting period of the query
- `date_to`
- `max_cloud_cover`
- `result_number`
- `name_filter`
- `coordinate_list`
- `progress_message`
- `proxy_host`
- `proxy_port`
- `proxy_user`
- `proxy_password`

**Returns**

object `OutputManger`

`remotior_sensus.tools.download_products.query_nasa_cmr`(*product*, *date\_from*, *date\_to*,  
*max\_cloud\_cover=100*,  
*result\_number=50*, *name\_filter=None*,  
*coordinate\_list=None*,  
*progress\_message=True*,  
*proxy\_host=None*, *proxy\_port=None*,  
*proxy\_user=None*,  
*proxy\_password=None*) →  
*OutputManager* (page 96)

Perform the query of NASA CMR.

This tool performs the query of NASA CMR Search [https://cmr.earthdata.nasa.gov/search/site/search\\_api\\_docs.html](https://cmr.earthdata.nasa.gov/search/site/search_api_docs.html).

### Parameters

- **product**
- **date\_from** – date defining the starting period of the query
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**
- **coordinate\_list**
- **progress\_message**
- **proxy\_host**
- **proxy\_port**
- **proxy\_user**
- **proxy\_password**

### Returns

object OutputManger

```
remotior_sensus.tools.download_products.query_sentinel2_mpc(date_from, date_to,  
max_cloud_cover=100,  
result_number=50,  
name_filter=None,  
coordinate_list=None,  
progress_message=True,  
proxy_host=None,  
proxy_port=None,  
proxy_user=None,  
proxy_password=None) →  
OutputManager (page 96)
```

Perform the query of Sentinel-2 from Microsoft Planetary Computer.

This tool performs the query from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>.

### Parameters

- **date\_from** – date defining the starting period of the query
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**
- **coordinate\_list**
- **progress\_message**
- **proxy\_host**
- **proxy\_port**
- **proxy\_user**
- **proxy\_password**

**Returns**object `OutputManger`

`remotior_sensus.tools.download_products.query_sentinel_2_database`(*date\_from*, *date\_to*, *max\_cloud\_cover*=100, *result\_number*=50, *name\_filter*=None, *coordinate\_list*=None, *progress\_message*=True, *copernicus\_user*=None, *copernicus\_password*=None, *proxy\_host*=None, *proxy\_port*=None, *proxy\_user*=None, *proxy\_password*=None)  
 → *OutputManager*  
 (page 96)

Perform the query of Sentinel-2 database.

This tool performs the query of Sentinel-2 database.

Query using Copernicus Data Space Ecosystem API <https://documentation.dataspace.copernicus.eu/#/APIs/OData> (from <https://documentation.dataspace.copernicus.eu>: ‘Copernicus Data Space Ecosystem represents an overall and comprehensive data ecosystem accessible via web portal, applications and APIs. ... The Copernicus Data Space Ecosystem provides the essential data and service offering for everyone to use, for commercial and non-commercial purposes’).

Sentinel-2 metadata are downloaded through the following Google service: <https://storage.googleapis.com/gcp-public-data-sentinel-2> .

**Parameters**

- **date\_from** – date defining the starting period of the query.
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**
- **coordinate\_list** – list [left, top, right, bottom] WGS84 coordinates.
- **progress\_message** – progress message
- **copernicus\_user**
- **copernicus\_password**
- **proxy\_host** – proxy host.
- **proxy\_port** – proxy port.
- **proxy\_user** – proxy user.
- **proxy\_password** – proxy password.

**Returns**

object *OutputManager*() (page 96)

`remotior_sensus.tools.download_products.search`(*product, date\_from, date\_to, max\_cloud\_cover=100, result\_number=50, name\_filter=None, coordinate\_list=None, progress\_message=True, proxy\_host=None, proxy\_port=None, proxy\_user=None, proxy\_password=None, copernicus\_user=None, copernicus\_password=None*) → *OutputManager* (page 96)

Perform the query of image databases.

This tool performs the query of image products, currently Landsat, Sentinel-2, Harmonized Landsat Sentinel-2.

Sentinel-2 data can be searched from multiple sources.

Query using Copernicus Data Space Ecosystem API <https://documentation.dataspace.copernicus.eu/#/APIs/OData> (from <https://documentation.dataspace.copernicus.eu>: ‘Copernicus Data Space Ecosystem represents an overall and comprehensive data ecosystem accessible via web portal, applications and APIs. ... The Copernicus Data Space Ecosystem provides the essential data and service offering for everyone to use, for commercial and non-commercial purposes’).

Sentinel-2 metadata are downloaded through the following Google service: <https://storage.googleapis.com/gcp-public-data-sentinel-2>.

Alternatively, query the collections from Microsoft Planetary Computer <https://planetarycomputer.microsoft.com>

Performs the query of Harmonized Landsat Sentinel-2 through NASA CMR Search [https://cmr.earthdata.nasa.gov/search/site/search\\_api\\_docs.html](https://cmr.earthdata.nasa.gov/search/site/search_api_docs.html).

### Parameters

- **product** – product name from configurations.product\_list
- **date\_from** – date defining the starting period of the query.
- **date\_to**
- **max\_cloud\_cover**
- **result\_number**
- **name\_filter**
- **coordinate\_list** – list [left, top, right, bottom] WGS84 coordinates.
- **progress\_message** – progress message
- **copernicus\_user**
- **copernicus\_password**
- **proxy\_host** – proxy host.
- **proxy\_port** – proxy port.
- **proxy\_user** – proxy user.
- **proxy\_password** – proxy password.

### Returns

object *OutputManager*() (page 96)

## remotior\_sensus.tools.mosaic module

Band mosaic.

This tool performs the mosaic of single bands, or multiple BandSets. Corresponding bands in two or more BandSet are merged into a single raster for each band, covering the extent of input bands. For instance, this is useful to

mosaic several multiband images together, obtaining a multispectral mosaic of bands (e.g., the first band of the mosaic corresponds to all the first bands of input images).

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> file_list = ['file1_b1.tif', 'file2_b1.tif']
>>> mosaic_bands = rs.mosaic(input_bands=file_list, output_path='output_directory')
```

`remotior_sensus.tools.mosaic.mosaic`(*input\_bands*: list | int | [BandSet](#) (page 59), *output\_path*: None | str = None, *overwrite*: bool | None = False, *prefix*: str | None = "", *nodata\_value*: None | int = None, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *virtual\_output*: bool | None = False, *output\_name*: None | str = None, *reference\_raster\_crs*: None | str = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Mosaic bands.

This tool performs the mosaic of corresponding bands from multiple [BandSets](#). A new raster is created for each band, named as `output_name` or first band name, and followed by band number.

#### Parameters

- **input\_bands** – list of paths of input rasters, or number of [BandSet](#), or [BandSet](#) object.
- **output\_path** – string of output path directory.
- **overwrite** – if True, output overwrites existing files.
- **prefix** – optional string for output name prefix.
- **nodata\_value** – value to be considered as nodata.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts.
- **output\_name** – string used as general name for all output bands.
- **reference\_raster\_crs** – path to a raster to be used as crs reference; if None, the first band is used as reference.
- **bandset\_catalog** – optional type [BandSetCatalog](#) for [BandSet](#) number.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object [OutputManager\(\)](#) (page 96) with

- `paths` = output list

#### Examples

Perform the mosaic of three [BandSets](#)

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
>>> # create three BandSets
>>> file_list_1 = ['file1_b1.tif', 'file1_b2.tif', 'file1_b3.tif']
>>> file_list_2 = ['file2_b1.tif', 'file2_b2.tif', 'file2_b3.tif']
>>> file_list_3 = ['file3_b1.tif', 'file3_b2.tif', 'file3_b3.tif']
>>> catalog.create_bandset(file_list_1, bandset_number=1)
>>> catalog.create_bandset(file_list_2, bandset_number=2)
>>> catalog.create_bandset(file_list_3, bandset_number=3)
>>> # start the process
>>> mosaic_bands = rs.mosaic(input_bands=[1, 2, 3],
... output_path='output_directory', bandset_catalog=catalog)
```

### remotior\_sensus.tools.preprocess\_products module

Perform the preprocessing of products.

```
remotior_sensus.tools.preprocess_products.create_product_table(input_path,
                                                                metadata_file_path=None,
                                                                product=None,
                                                                nodata_value=None,
                                                                sensor=None,
                                                                acquisition_date=None)
```

```
remotior_sensus.tools.preprocess_products.perform_preprocess(product_table, output_path,
                                                             dos1_correction=False,
                                                             add_bandset=None,
                                                             output_prefix="", n_processes:
int | None = None,
                                                             available_ram: int | None =
None, bandset_catalog:
BandSetCatalog (page 70) |
None = None,
                                                             progress_message=True) →
OutputManager (page 96)
```

Preprocess products.

Perform preprocessing based on product table.

#### Parameters

- **product\_table** – product table object.
- **output\_path** – string of output path directory.
- **dos1\_correction** – if True, perform DOS1 correction.
- **add\_bandset** – if True, create a new bandset and add output bands to it; if False, add output bands to current bandset.
- **output\_prefix** – optional string for output name prefix.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – BandSetCatalog object.
- **progress\_message** – progress message.

#### Returns

Object `OutputManager()` (page 96) with

- paths = output list

```
remotior_sensus.tools.preprocess_products.preprocess(input_path, output_path,
                                                    metadata_file_path=None,
                                                    add_bandset=None, product=None,
                                                    nodata_value=None, sensor=None,
                                                    acquisition_date=None,
                                                    dos1_correction=False, output_prefix="",
                                                    n_processes: int | None = None,
                                                    bandset_catalog: BandSetCatalog
                                                    (page 70) | None = None, available_ram:
                                                    int | None = None,
                                                    progress_message=True) →
                                                    OutputManager (page 96)
```

Create table and preprocess products.

Perform image conversion to reflectance of several products.

Can calculate DOS1 corrected reflectance (Sobrino, J. et al., 2004. Land surface temperature retrieval from LANDSAT TM 5. Remote Sensing of Environment, Elsevier, 90, 434-440) approximating path radiance to path reflectance for level 1 data:

$$\text{TOA reflectance} = \text{DN} * \text{reflectance\_scale} + \text{reflectance\_offset}$$

$$\text{path reflectance } p = \text{DNm} - \text{Dark Object reflectance} = \text{DNm} * \text{reflectance\_scale} + \text{reflectance\_offset} - 0.01$$

$$\text{land surface reflectance} = \text{TOA reflectance} - p = (\text{DN} * \text{reflectance\_scale}) - (\text{DNm} * \text{reflectance\_scale} - 0.01)$$

Landsat's data Collection 1 and 2 Level 1T Landsat 8-9 TOA reflectance proportional to exo-atmospheric solar irradiance in each band and the Earth-Sun distance (USGS, 2021. Landsat 8-9 Calibration and Validation (Cal/Val) Algorithm Description Document (ADD). Version 4.0. Department of the Interior U.S. Geological Survey, South Dakota)

$$\text{TOA reflectance with correction for the sun angle} = \text{DN} * \text{Reflectance multiplicative scaling factor} + \text{Reflectance additive scaling factor} / \sin(\text{Sun elevation})$$

Level 2S

$$\text{Surface reflectance} = \text{DN} * \text{Reflectance multiplicative scaling factor} + \text{Reflectance additive scaling factor}$$

Sentinel-2 data Level 1C

$$\text{TOA reflectance} = \text{DN} / \text{QUANTIFICATION VALUE} + \text{OFFSET}$$

Level 2S

$$\text{Surface reflectance} = \text{DN} / \text{QUANTIFICATION VALUE} + \text{OFFSET}$$

### Parameters

- **input\_path** – path containing the raster bands.
- **output\_path** – string of output path directory.
- **metadata\_file\_path** – optional metadata file path.
- **dos1\_correction** – if True, perform DOS1 correction.
- **add\_bandset** – if True, create a new bandset and add output bands to it; if False, add output bands to current bandset.
- **product** – product name.
- **nodata\_value** – nodata value.

- **sensor** – sensor name.
- **acquisition\_date** – acquisition date.
- **output\_prefix** – optional string for output name prefix.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – BandSetCatalog object.
- **progress\_message** – progress message.

#### Returns

Object `OutputManager()` (page 96) with

- `paths` = output list

### remotior\_sensus.tools.raster\_edit module

Raster edit.

This tool allows for the direct editing of a raster band. Warning, this tool edits the original input raster.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> edit = rs.raster_edit(raster_path='input_path',
... vector_path='vector_path')
```

`remotior_sensus.tools.raster_edit.check_expression(expression, constant_value)`

`remotior_sensus.tools.raster_edit.raster_edit(raster_path: str, vector_path: None | str = None, field_name: None | str = None, expression: None | str = None, constant_value: None | int | float = None, old_array: ndarray | None = None, column_start: None | int = None, row_start: None | int = None, available_ram: None | int = None, progress_message: bool | None = True) → OutputManager (page 96)`

Edit a raster band based on a vector file.

This tool allows for editing the values of a raster using a vector file. All pixel intersecting the vector will be edited with a new value. New pixel values can be a constant value or defined by a custom expression defining a condition. The input raster is directly edited, without producing a new file.

#### Parameters

- **raster\_path** – path of raster used as input.
- **vector\_path** – string of vector path (optional for undo operation).
- **field\_name** – string of vector field name.
- **expression** – optional conditional expression; pixels are edited if intersecting the vector and the expression is True; the variable “raster” is used to refer to the raster pixel values; e.g. where(“raster” > 500, 10, “raster”).
- **constant\_value** – optional new value for pixels.
- **old\_array** – optional previous array for undo operation.
- **column\_start** – optional starting column for undo operation.

- **row\_start** – optional starting row for undo operation.
- **available\_ram** – number of megabytes of RAM available to processes.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object *OutputManager()* (page 96) with

- extra = {'old\_array': previous array for undo operation, 'column\_start': starting column for undo operation, 'row\_start': starting row for undo operation}

#### Examples

##### Perform the edit of a raster

```
>>> edit_1 = raster_edit(raster_path='input_path',
... vector_path='output_path')
```

##### Perform the undo of edit of a raster

```
>>> edit_2 = raster_edit(raster_path='input_path',
... column_start=edit_1.extra['column_start'],
... row_start=edit_1.extra['row_start'],
... old_array=edit_1.extra['old_array']
... )
```

##### Perform the edit of a raster with condition

```
>>> edit_3 = raster_edit(raster_path='input_path',
... vector_path='output_path',
... expression='where("raster" > 500, 10, "raster")'
... )
```

## remotior\_sensus.tools.raster\_reclassification module

Raster reclassification.

This tool allows for the reclassification of a raster based on a reclassification table.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> reclassification = rs.raster_reclassification(raster_path='file1.tif',
... output_path='output.tif',
... reclassification_table=[[1, -10], ['nan', 6000]])
```

```
remotior_sensus.tools.raster_reclassification.raster_reclassification(raster_path: str,  
                                                                    output_path: None |  
                                                                    str = None,  
                                                                    overwrite: bool |  
                                                                    None = False, re-  
                                                                    classification_table:  
                                                                    list | array | None =  
                                                                    None, csv_path:  
                                                                    None | str = None,  
                                                                    separator: str | None  
                                                                    = ',',  
                                                                    output_data_type:  
                                                                    None | str = None,  
                                                                    extent_list: list |  
                                                                    None = None,  
                                                                    n_processes: None |  
                                                                    int = None,  
                                                                    available_ram: None  
                                                                    | int = None,  
                                                                    virtual_output: bool  
                                                                    | None = None,  
                                                                    progress_message:  
                                                                    bool | None = True)  
→ OutputManager  
(page 96)
```

Performs raster reclassification.

This tool reclassifies a raster based on a reclassification table. The reclassification table is defined by two columns: old values and new values. Old values define the values of the raster to be reclassified to new values. Old values can be integer numbers or conditions selecting ranges of values.

#### Parameters

- **raster\_path** – path of raster used as input.
- **output\_path** – string of output path.
- **overwrite** – if True, output overwrites existing files.
- **reclassification\_table** – table of values for reclassification or list of values `[[old_value, new_value], ...]`; if None, `csv_path` is used.
- **csv\_path** – path to a csv file containing the reclassification table; used if `reclassification_table` is None.
- **separator** – separator character for csv file; default is comma separated.
- **output\_data\_type** – set output data type such as 'Float32' or 'Int32'; if None, input data type is used.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **virtual\_output** – if True (and `output_path` is directory), save output as virtual raster of multiprocessing parts.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

Object [OutputManager\(\)](#) (page 96) with

- path = output path

### Examples

#### Perform the reclassification using a csv file containing the reclassification values

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> reclassification = rs.raster_reclassification(raster_path='file1.tif'
↳ ,output_path='output.tif',csv_path='file.csv')
```

```
remotior_sensus.tools.raster_reclassification.unique_values_table(raster_path: str,
                                                                n_processes: None | int =
                                                                None, available_ram:
                                                                None | int = None,
                                                                incremental: bool | None
                                                                = False,
                                                                progress_message: bool |
                                                                None = True)
```

Calculate unique values from raster.

#### remotior\_sensus.tools.raster\_report module

Raster report.

This tool allows for the calculation of a report providing information extracted from a raster.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> report = rs.raster_report(raster_path='file.tif',output_path='report.csv')
```

```
remotior_sensus.tools.raster_report.raster_report(raster_path: str, output_path: None | str =
                                                                None, nodata_value: None | int = None,
                                                                extent_list: list | None = None, n_processes:
                                                                None | int = None, available_ram: None | int =
                                                                None, progress_message: bool | None = True)
→ OutputManager (page 96)
```

Calculation of a report providing information extracted from a raster.

This tool allows for the calculation of a report providing information such as pixel count, area per class and percentage of the total area. The output is a csv file. This tool is intended for integer rasters.

#### Parameters

- **raster\_path** – path of raster used as input.
- **output\_path** – string of output path.
- **nodata\_value** – value to be considered as nodata.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.

- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object *OutputManager()* (page 96) with

- path = output path

#### Examples

Perform the report of a raster

```
>>> raster_report(raster_path='file.tif', output_path='report.csv')
```

### remotior\_sensus.tools.raster\_split module

Raster split.

This tool allows for splitting a raster to single bands.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> split = rs.raster_split(raster_path='input_path',
... output_path='output_path')
```

*remotior\_sensus.tools.raster\_split.raster\_split(raster\_path: str, output\_path: str | None = None, prefix: None | str = None, extent\_list: list | None = None, n\_processes: None | int = None, virtual\_output: bool | None = None, progress\_message: bool | None = True) → OutputManager (page 96)*

Split a multiband raster to single bands.

This tool allows for splitting a multiband raster to single bands.

#### Parameters

- **raster\_path** – path of raster used as input.
- **output\_path** – string of output directory path.
- **prefix** – optional string for output name prefix.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **virtual\_output** – if True (and output\_path is directory), save output as virtual raster.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object *OutputManager()* (page 96) with

- path = output path

**Examples****Perform the split of a raster**

```
>>> split = raster_split(raster_path='input_path',
... output_path='output_path')
```

**remotior\_sensus.tools.raster\_zonal\_stats module**

Raster zonal stats.

This tool allows for calculating statistics of a raster intersecting a vector.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> statistics = rs.raster_zonal_stats(
... raster_path='input_path', reference_path='input_vector_path',
... vector_field='field_name', output_path='output_path',
... stat_names=['Sum', 'Mean'])
```

```
remotior_sensus.tools.raster_zonal_stats.raster_zonal_stats(raster_path: str, reference_path:
str, vector_field: str | None =
None, output_path: str | None =
None, stat_names: str | list | None
= None, stat_percentile: int | str |
list | None = None, extent_list: list
| None = None, n_processes:
None | int = None, available_ram:
None | int = None,
progress_message: bool | None =
True) → OutputManager
(page 96)
```

Raster zonal stats based on a polygon vector field.

This tool allows for calculating statistics of a raster intersecting a vector. For each unique value in the vector field, one or more statistics can be calculated based on raster pixel values intersecting the vector polygons. The output is a csv file and a numpy records table including the statistics for each unique value in the vector field. Available functions are:

- Count
- Max
- Mean
- Median
- Min
- Percentile
- StandardDeviation
- Sum

**Parameters**

- **raster\_path** – path of raster used as input.

- **reference\_path** – path of the vector or raster file used as reference input.
- **vector\_field** – the name of the vector field used as reference value.
- **stat\_names** – statistic name as in configurations.statistics\_list.
- **stat\_percentile** – integer value for percentile parameter.
- **output\_path** – string of output directory path.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object *OutputManager()* (page 96) with

- path = output csv path
- extra = {'table': table as numpy records}

#### Examples

##### Perform the calculation

```
>>> stats = raster_zonal_stats(
... raster_path='input_path', reference_path='input_vector_path',
... vector_field='field_name', output_path='output_path',
... stat_names=['Percentile', 'Max', 'Min'], stat_percentile=[1, 99]
... )
```

#### remotior\_sensus.tools.raster\_to\_vector module

Raster to vector.

This tool allows for the conversion from raster to vector. A new geopackage is created from the raster conversion.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> vector = rs.raster_to_vector(raster_path='file.tif', output_path='vector.gpkg')
```

`remotior_sensus.tools.raster_to_vector.raster_to_vector`(*raster\_path*, *output\_path*: *None* | *str* = *None*, *dissolve*: *bool* | *None* = *None*, *field\_name*: *None* | *str* = *None*, *extent\_list*: *list* | *None* = *None*, *n\_processes*: *None* | *int* = *None*, *available\_ram*: *None* | *int* = *None*, *progress\_message*: *bool* | *None* = *True*) → *OutputManager* (page 96)

Performs the conversion from raster to vector.

This tool performs the conversion from raster to vector. Parallel processes are used for the conversion, resulting in a vector output which is split as many in portions as the process numbers. The argument `dissolve` allows for merging these portions, but it requires additional processing time depending on vector size.

### Parameters

- **raster\_path** – path of raster used as input.
- **output\_path** – string of output path.
- **dissolve** – if True, dissolve adjacent polygons having the same values; if False, polygons are not dissolved and the process is rapider.
- **field\_name** – name of the output vector field to store raster values (default = DN).
- **extent\_list** – list of boundary coordinates left top right bottom.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

### Returns

object `OutputManager()` (page 96) with

- path = output path

### Examples

#### Perform the conversion to vector of a raster

```
>>> raster_to_vector(raster_path='file.tif', output_path='vector.gpkg')
```

### remotior\_sensus.tools.vector\_to\_raster module

Vector to raster.

This tool allows for the conversion from vector polygons to raster.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # start the process
>>> vector = rs.vector_to_raster(vector_path='file.gpkg',
...     output_path='vector.tif')
```

`remotior_sensus.tools.vector_to_raster.vector_to_raster`(*vector\_path*: str, *align\_raster*: str | [BandSet](#) (page 59) | int, *vector\_field*: None | str = None, *constant*: None | int = None, *pixel\_size*: None | int = None, *output\_path*: None | str = None, *method*: None | str = None, *area\_precision*: int | None = 20, *resample*='mode', *nodata\_value*: None | int = None, *minimum\_extent*: bool | None = True, *extent\_list*: list | None = None, *output\_format*='GTiff', *compress*=None, *compress\_format*=None, *n\_processes*: None | int = None, *available\_ram*: None | int = None, *bandset\_catalog*: [BandSetCatalog](#) (page 70) | None = None, *progress\_message*: bool | None = True) → [OutputManager](#) (page 96)

Performs the conversion from vector to raster.

This tool performs the conversion from vector polygons to raster.

#### Parameters

- **vector\_path** – path of vector used as input.
- **align\_raster** – optional string path of raster used for aligning output pixels and projections; it can also be a [BandSet](#) or an integer number of a [BandSet](#) in a [Catalog](#).
- **output\_path** – string of output path.
- **vector\_field** – the name of the field used as reference value.
- **constant** – integer value used as reference for all the polygons.
- **pixel\_size** – size of pixel of output raster.
- **minimum\_extent** – if True, raster has the minimum vector extent; if False, the extent is the same as the align raster.
- **extent\_list** – list of boundary coordinates left top right bottom.
- **output\_format** – output format, default GTiff
- **method** – method of conversion, default pixel\_center, other methods are all\_touched for burning all pixels touched or area\_based for burning values based on area proportion.
- **area\_precision** – for area\_based method, the higher the value, the more is the precision in area proportion calculation.
- **resample** – type for resample when method is area\_based.
- **compress** – if True, compress the output raster.
- **compress\_format** – compress format.
- **nodata\_value** – value to be considered as nodata.
- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **bandset\_catalog** – [BandSetCatalog](#) object.
- **progress\_message** – if True then start progress message, if False does not start the progress message (useful if launched from other tools).

#### Returns

object `OutputManager()` (page 96) with

- path = output path

### Examples

Perform the conversion to raster of a vector

```
>>> vector_to_raster(vector_path='file.gpkg', output_path='vector.tif')
```

## Module contents

### 1.7 Core Modules

The following are the core modules.

#### 1.7.1 remotior\_sensus.core package

##### Submodules

##### remotior\_sensus.core.bandset\_catalog module

**class** `remotior_sensus.core.bandset_catalog.BandSet` (*bandset\_uid, bands\_list=None, name=None, date=None, root\_directory=None, crs=None, box\_coordinate\_list=None, catalog=None*)

Bases: object

Manages band sets.

This module allows for managing bands in a BandSet.

##### bands

BandSet of band tables.

##### get

alias for `get_band` function.

### Examples

Create a BandSet

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> file_list = ['file_1.tif', 'file_2.tif', 'file_3.tif']
>>> bandset = rs.bandset.create(file_list)
```

Get the first band

```
>>> band_1 = bandset.get_band(1)
```

**\_\_init\_\_** (*bandset\_uid, bands\_list=None, name=None, date=None, root\_directory=None, crs=None, box\_coordinate\_list=None, catalog=None*)

Initializes a BandSet.

Initializes a BandSet defining a unique ID. One should use the create method for creating new BandSets.

##### Parameters

- **bandset\_uid** – unique BandSet ID.
- **bands\_list** – list of band tables.
- **name** – optional BandSet name.
- **date** – optional BandSet date.
- **root\_directory** – optional BandSet root directory for relative path.
- **crs** – BandSet coordinate reference system.
- **box\_coordinate\_list** – list of coordinates [left, top, right, bottom] to create a virtual subset.
- **catalog** – BandSet Catalog

### Examples

#### Initialize a BandSet

```
>>> BandSet.create(name=name, box_coordinate_list=box_coordinate_list)
```

```
add_new_band(path: str, band_number: int | None = None, raster_band=None, band_name=None,
             date=None, root_directory=None, multiplicative_factor=None, additive_factor=None,
             wavelength=None, unit=None)
```

Adds new band to a BandSet.

Adds a new band to a BandSet with the option to set the band number for the position in the BandSet order.

#### Parameters

- **path** – file path.
- **band\_number** – sets the position of the band in BandSet order.
- **raster\_band** – number of band for multiband rasters.
- **band\_name** – name of raster used for band.
- **date** – single date (as YYYY-MM-DD).
- **multiplicative\_factor** – multiplicative factor.
- **additive\_factor** – additive factor.
- **wavelength** – center wavelength.
- **unit** – wavelength unit.
- **root\_directory** – root directory for relative path.

### Examples

#### Add a new band

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = BandSet()
>>> bandset.add_new_band(
... path=path, band_number=band_number, raster_band=raster_band,
... band_name=band_name, date=date, root_directory=root_directory,
... multiplicative_factor=multiplicative_factor,
... additive_factor=additive_factor, wavelength=wavelength, unit=unit
... )
```

**property box\_coordinate\_list**

Optional BandSet box coordinate list for virtual subset.

**Type**

list

**calc(\*args, \*\*kwargs)**

Executes a calculation.

Executes a calculation directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function. Bands in the BandSet can be referred in the expressions such as “b1” or “b2”; also band alias such as “#RED#” and expression alias such as #NDVI# can be used.

**Parameters**

**kwargs** – See `band_calc()` (page 8).

**Returns**

The output of the function.

**Examples**

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(
...     ['file1.tif', 'file2.tif'], wavelengths=['Sentinel-2'],
... )
```

Calculation of sum of the first two bands and saving the output in temporary directory

```
>>> output_object = bandset.calc('"b1" + "b2"')
```

Calculation of NDVI

```
>>> output_object = bandset.calc(output_path='output.tif',
...     expression_string='("#NIR#" - "#RED#") / ("#NIR#" + "#RED#")'
... )
```

**classification(\*args, \*\*kwargs)**

Executes a classification.

Executes a classification directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.

**Parameters**

**kwargs** – See `band_classification()` (page 11).

**Returns**

The output of the function.

**combination(\*args, \*\*kwargs)**

Band combination.

Combines classifications directly from the BandSet, in order to get a raster where each value corresponds to a combination of class values. The arguments are related to the function.

**Parameters**

**kwargs** – See `band_combination()` (page 22).

**Returns**

The output of the function.

**Examples****Given that a session was previously started**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

**Combination using two rasters having paths path\_1 and path\_2**

```
>>> combination = bandset.combination(output_path='output_path')
```

**classmethod create**(*paths: str | list | None = None, band\_names: list | None = None, wavelengths: list | None = None, unit: None | str = None, multiplicative\_factors: list | None = None, additive\_factors: list | None = None, dates: list | None = None, root\_directory: None | str = None, box\_coordinate\_list: list | None = None, name: None | str = None, catalog=None*)

Creates a BandSet.

This method creates a BandSet defined by input files. Raster properties are derived from files to populate the table of bands.

**Parameters**

- **catalog** – BandSet Catalog object.
- **name** – BandSet name.
- **paths** – list of file paths or a string of directory path; also, a list of directory path and name filter is accepted.
- **band\_names** – list of raster names used for identifying the bands, if None then the names are automatically extracted from file names.
- **wavelengths** – list of center wavelengths of bands or string of sensor names (also partial).
- **unit** – wavelength unit.
- **multiplicative\_factors** – multiplicative factors for bands during calculations.
- **additive\_factors** – additive factors for bands during calculations.
- **dates** – list of date strings, or single date string (format YYYY-MM-DD) or string defined in configurations date\_auto to detect date from directory name.
- **root\_directory** – root directory for relative path.
- **box\_coordinate\_list** – list of coordinates [left, top, right, bottom] to create a virtual subset.

**Returns**

returns BandSet.

**Examples****Given that a session was previously started**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # set lists of files, names and center wavelength
>>> file = ['file_1.tif', 'file_2.tif', 'file_3.tif']
>>> names = ['name_1', 'name_2', 'name_3']
>>> wavelength = [0.6, 0.7, 0.8]
>>> # create a BandSet
>>> bandset = rs.bandset.create(file, band_names=names,
↳wavelengths=wavelength)
```

Passing a directory with file name filter and the wavelength from satellite name.

```
>>> bandset = rs.bandset.create(['directory_path', 'tif'],
↳wavelengths='Sentinel-2')
```

#### property crs

crs.

##### Type

str

#### property date

Optional date.

#### dilation(\*args, \*\*kwargs)

Band dilation.

Band dilation directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.

##### Parameters

**kwargs** – See `band_dilation()` (page 24).

##### Returns

The output of the function.

#### Examples

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

##### Dilation

```
>>> dilation = bandset.dilation(output_path='directory_path',
... value_list=[1, 2], size=5)
```

#### erosion(\*args, \*\*kwargs)

Band erosion.

Band erosion directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.

##### Parameters

**kwargs** – See `band_erosion()` (page 26).

**Returns**

The output of the function.

**Examples**

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

Erosion

```
>>> erosion = bandset.erosion(output_path='directory_path',
...     value_list=[1, 2], size=1)
```

**execute**(function, \*args, \*\*kwargs)

Executes a function.

Executes a functions directly from the BandSet, passing the argument input\_bands. The arguments are related to the function.

**Parameters**

**function** – the function to be executed.

**Returns**

The output of the function.

**Examples**

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(
...     ['file1.tif', 'file2.tif'], wavelengths=['Sentinel-2'],
... )
```

Calculation of sum of the first two bands

```
>>> output_object = bandset.execute(
...     rs.band_calc, output_path='output.tif', expression_string='
→ "b1" + "b2"
... )
```

Calculation of NDVI

```
>>> output_object = bandset.execute(
...     rs.band_calc, output_path='output.tif',
...     expression_string='("#NIR#" - "#RED#") / ("#NIR#" + "#RED#")'
... )
```

Calculation of band combination

```
>>> output_object = bandset.execute(rs.band_combination, output_path=
→ 'output.tif')
```

**export\_as\_xml**(*output\_path=None*)

Exports a BandSet as xml.

Exports a BandSet bands and attributes.

#### Examples

##### Export a BandSet.

```
>>> bandset = BandSet()
>>> # reset
>>> bandset.export_as_xml()
```

**find\_values\_in\_list**(*attribute, value\_list, output\_attribute=None*) → list

Adds new band to a BandSet.

Finds BandSet values in a list and return a band attribute or band numbers.

#### Parameters

- **attribute** – attribute name for identification.
- **value\_list** – attribute value list for identification.
- **output\_attribute** – attribute name of desired output; if None returns the band number.

#### Returns

returns list of band attributes.

#### Examples

##### Find values from wavelength attribute

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = BandSet()
>>> bandset_values = bandset.find_values_in_list(
... attribute='wavelength', value_list=[0.6, 0.7],
... output_attribute='path'
... )
```

**static generate\_uid**() → str

Generates unique ID for BandSet

#### Returns

returns table of bands.

**get\_absolute\_path**(*band\_number*) → str

Gets the absolute path of band.

**get\_absolute\_paths**() → list

Gets the list of absolute paths.

**get\_band**(*number=None*) → array

Gets a band.

Gets a band by number.

**Parameters**

**number** – band number.

**Returns**

the band table; if number is None returns all the bands; returns None if band number is not found.

**Examples****Get bands by number**

```
>>> bandset = BandSet()
>>> # get first band
>>> band = bandset.get_band(1)
>>> # band x size
>>> band_x_size = band.x_size
>>> # get band nodata directly
>>> band_nodata = bandset.get_band(1).nodata
```

**get\_band\_alias()** → list

Gets bands alias (with band number) used in band\_calc

**Returns**

the list of band aliases.

**get\_band\_attributes(attribute: str | None = None)** → list

Gets band attributes.

Gets an attribute of bands.

**Parameters**

**attribute** – attribute name.

**Returns**

returns list of attributes; if attribute is None returns the bands; if attribute is not found returns None.

**Examples****Get band names**

```
>>> bandset = BandSet()
>>> names = bandset.get_band_attributes('name')
```

**get\_band\_by\_wavelength(wavelength: float, threshold: float | None = None, output\_as\_number=False)** → array

Gets band by wavelength.

Gets band by nearest wavelength.

**Parameters**

- **wavelength** – value of wavelength.
- **threshold** – threshold for wavelength identification, identifying bands within wavelength +- threshold; if None, the nearest value is returned.
- **output\_as\_number** – if True returns the number of the band, if False returns the band table.

**Returns**

returns band table.

**Examples****Get band by wavelength**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = BandSet()
>>> # get band by nearest wavelength
>>> band_x = bandset.get_band_by_wavelength(
>>> wavelength=0.7, threshold=0.1
>>> )
```

**get\_band\_count()** → int

Gets the count of bands.

**get\_bands\_by\_attributes**(*attribute: str, attribute\_value, output\_as\_number=False*) → array

Gets bands by attribute.

Gets bands identified by an attribute value (identified bands have the attribute value equal to the attribute\_value).

**Parameters**

- **attribute** – attribute name.
- **attribute\_value** – attribute value.
- **output\_as\_number** – if True returns the number of the band, if False returns the band table.

**Returns**

if output\_number is True, returns list of band number; if output\_number is False, returns bands identified by attribute; returns None if no band has the attribute value.

**Examples****Get bands by attributes**

```
>>> bandset = BandSet()
>>> band_x = bandset.get_bands_by_attributes('wavelength', 0.8)
```

**get\_path**(*band\_number*) → str | None

Gets the absolute path of band.

**get\_paths**() → list

Gets the list of bands.

**get\_raster\_band\_list**() → list

Gets the list of raster bands.

**get\_wavelength\_units**() → list

Gets the list of wavelength units.

**get\_wavelengths**() → list

Gets the list of center wavelength.

**import\_as\_xml**(*xml\_path*)

Imports a BandSet as xml.

Imports a BandSet bands and attributes.

#### Examples

##### Import a BandSet

```
>>> bandset = BandSet()
>>> # reset
>>> bandset.import_as_xml('xml_path')
```

**property name**

Optional BandSet name.

**Type**

str

**neighbor\_pixels**(\*args, \*\*kwargs)

Band neighbor pixels.

Band neighbor pixels directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.

**Parameters**

**kwargs** – See [band\\_neighbor\\_pixels\(\)](#) (page 28).

**Returns**

The output of the function.

#### Examples

##### Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

##### Neighbor pixels

```
>>> neighbor = bandset.neighbor_pixels(output_path='directory_path',
... size=10, circular_structure=True, stat_name='Sum')
```

**pca**(\*args, \*\*kwargs)

Band PCA.

Band PCA directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.

**Parameters**

**kwargs** – See [band\\_pca\(\)](#) (page 30).

**Returns**

The output of the function.

**Examples****Given that a session was previously started**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

**PCA**

```
>>> pca = bandset.pca(output_path='directory_path')
```

**print()**

Prints a BandSet.

Prints a BandSet bands and attributes.

**Examples****Print a BandSet.**

```
>>> bandset = BandSet()
>>> # reset
>>> bandset.print()
```

**reset()**

Resets a BandSet.

Resets a BandSet destroying bands and attributes.

**Examples****Reset a BandSet**

```
>>> bandset = BandSet()
>>> # reset
>>> bandset.reset()
```

**property root\_directory**

Optional BandSet root directory for relative path.

**Type**

str

**sieve(\*args, \*\*kwargs)**

Band sieve.

Band sieve directly from the BandSet, passing the argument `input_bands`. The arguments are related to the function.**Parameters****kwargs** – See `band_sieve()` (page 33).**Returns**

The output of the function.

**Examples**

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = rs.bandset.create(['file1.tif', 'file2.tif'])
```

Sieve

```
>>> sieve = bandset.sieve(output_path='directory_path', size=3)
```

**sort\_bands\_by\_name**(*keep\_wavelength\_order=True*)

Sorts band order by name

**sort\_bands\_by\_wavelength**()

Sorts band order by wavelength

**spectral\_range\_bands**(*output\_as\_number=True*) → list

Gets bands from spectral range.

Gets bands from spectral range blue, green, red, nir, swir\_1, swir\_2.

**Parameters**

**output\_as\_number** – if True returns the number of the band, if False returns the band table.

**Returns**

returns list of bands.

**Examples**

Gets bands from spectral range

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> bandset = BandSet()
>>> # spectral range bands
>>> (blue_band, green_band, red_band, nir_band, swir_1_band,
...  swir_2_band) = bandset.spectral_range_bands(
...  output_as_number=False)
```

**property uid**

Unique BandSet ID.

**Type**

str

**class** remotior\_sensus.core.bandset\_catalog.**BandSetCatalog**

Bases: object

Manages BandSets.

This class manages BandSets through a catalog, defining attributes and properties of BandSets.

**bandsets**

dictionary of the actual BandSets

**bandsets\_table**

table of BandSets containing the properties thereof

**get**

alias for get\_bandset

**Examples****Create a BandSet Catalog**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = rs.bandset_catalog()
```

**\_\_init\_\_()**

Initializes the catalog with an empty BandSet

**add\_band\_to\_bandset**(*path: str, bandset\_number: None | int = None, band\_number: None | int = None, raster\_band: None | int = None, band\_name: None | str = None, date: None | str = None, unit: None | str = None, root\_directory: None | str = None, multiplicative\_factor: None | int = None, additive\_factor: None | int = None, wavelength: None | float = None*)

Adds a new band to BandSet.

This function creates a new band and adds it to a BandSet.

**Parameters**

- **path** – file path.
- **band\_name** – raster name used for identifying the bands.
- **wavelength** – center wavelengths of band.
- **unit** – wavelength unit as string
- **multiplicative\_factor** – multiplicative factor for bands during calculations.
- **additive\_factor** – additive factors for band during calculations.
- **date** – date string (format YYYY-MM-DD).
- **bandset\_number** – number of the BandSet; if None, the band is added to the current BandSet.
- **root\_directory** – root directory for relative path.
- **raster\_band** – raster band number.
- **band\_number** – number of band in BandSet.

**Examples****Add a band to BandSet 1.**

```
>>> catalog = BandSetCatalog()
>>> catalog.add_band_to_bandset(
    path='file1.tif', bandset_number=1, band_number=1, raster_band=1
    ... )
```

**add\_bandset**(*bandset*: [BandSet](#) (page 59), *bandset\_number*: *None* | *int* = *None*, *insert*=*False*, *keep\_uid*=*False*)

Adds a BandSet to Catalog.

This function adds a previously created BandSet to BandSet Catalog.

#### Parameters

- **bandset** – the BandSet to be added.
- **bandset\_number** – number of BandSet; if *None*, current BandSet is used.
- **insert** – if *True* insert the BandSet at *bandset\_number* (other BandSets are moved), if *False* replace the BandSet number.
- **keep\_uid** – if *True*, keeps uid from the original bandset to the added one.

#### Examples

Insert a BandSet as BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> catalog.add_bandset(bandset_number=1, insert=True
... )
```

**build\_bandset\_band\_overview**(*bandset\_number*: *int* | *None* = *None*) → *bool*

Build bandset band overviews.

Build bandset band overviews as external files to faster the visualization.

#### Parameters

- **bandset\_number** – number of BandSet; if *None*, current BandSet is used.

#### Returns

True if successfull.

#### Examples

Build BandSet 1 overview.

```
>>> catalog = BandSetCatalog()
>>> catalog.build_bandset_band_overview(1)
```

**calculate\_scatter\_plot\_histogram**(*bandset\_number*: *int*, *band\_x*: *int*, *band\_y*: *int*, *vector\_path*: *str*) → *bool*

Calculate scatter plot histogram.

Calculate scatter plot histogram from two bands and a vector, useful for scatter plot display.

#### Parameters

- **bandset\_number** – number of BandSet; if *None*, current BandSet is used.
- **band\_x** – number of band x.
- **band\_y** – number of band y.
- **vector\_path** – path to the vector used for histogram calculation.

#### Returns

NumPy histogram.

**Examples****Calculate BandSet 1 scatter plot.**

```
>>> catalog = BandSetCatalog()
>>> catalog.calculate_scatter_plot_histogram(
... bandset_number= 1, band_x=1, band_y=1, vector_path='path')
```

**clear\_bandset**(*bandset\_number=None*)

Function to clear a BandSet.

**create\_band\_string\_list**(*bandset\_number: int | None = None*) → list

Creates band string list.

Creates band string list such as “bandset1b1” for all the bands in a BandSet. Used in tool [band\\_calc\(\)](#) (page 8).

**Parameters**

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Returns**

List of band string such as [“bandset1b1”, “bandset1b2”].

**Examples****Get BandSet 1 band string list.**

```
>>> catalog = BandSetCatalog()
>>> catalog.create_band_string_list(1)
```

**create\_bandset**(*paths: str | list | None = None, band\_names: list | None = None, wavelengths: list | None = None, unit: None | str = None, multiplicative\_factors: list | None = None, additive\_factors: list | None = None, date: list | None = None, bandset\_number: None | int = None, insert: bool | None = False, root\_directory: None | str = None, bandset\_name: None | str = None, box\_coordinate\_list: list | None = None*) → *BandSet* (page 59)

Creates a BandSet adding it to the catalog.

This function creates a BandSet adding it to the catalog, by inserting or replacing the BandSet at specific BandSet number. Wavelength is defined by providing a list of values for each band, or a string of sensors names as defined in configurations `sat_band_list` such as:

- Sentinel-2;
- Landsat 8;
- Landsat 5;
- ASTER.

Wavelength unit is defined by a string such as:

- band number unitless band order as defined in the BandSet;
- $\mu\text{m}$  (1 E-6m) micrometers;
- nm (1 E-9m) nanometers.

**Parameters**

- **paths** – list of file paths or a string of directory path; also, a list of directory path and name filter is accepted.
- **band\_names** – list of raster names used for identifying the bands, if None then the names are automatically extracted from file names.
- **wavelengths** – list of center wavelengths of bands or string of sensor names (also partial).
- **unit** – wavelength unit as string
- **multiplicative\_factors** – multiplicative factors for bands during calculations.
- **additive\_factors** – additive factors for bands during calculations.
- **date** – list of date strings, or single date string (format YYYY-MM-DD) or string defined in configurations date\_auto to detect date from directory name.
- **bandset\_number** – number of the BandSet, replacing an existing BandSet with the same number.
- **insert** – if True insert the BandSet at bandset\_number, if False replace the BandSet number.
- **root\_directory** – root directory for relative path.
- **bandset\_name** – name of the BandSet.
- **box\_coordinate\_list** – list of coordinates [left, top, right, bottom] to create a virtual subset.

#### Returns

The created BandSet.

#### Examples

Create a first BandSet from a file list with files inside a data directory, setting root\_directory, defining the BandSet date, and the wavelength from satellite name.

```
>>> catalog = BandSetCatalog()
>>> file_list = ['file1.tif', 'file2.tif', 'file3.tif']
>>> bandset_date = '2021-01-01'
>>> data_directory = 'data'
>>> bandset = catalog.create_bandset(
... paths=file_list, wavelengths=['Sentinel-2'], date=bandset_date,
... root_directory=data_directory
... )
```

Create a new BandSet from a file list with files inside a data directory (setting root\_directory), defining the BandSet date, and explicitly defining the BandSet number.

```
>>> catalog = BandSetCatalog()
>>> file_list = ['file1.tif', 'file2.tif', 'file3.tif']
>>> bandset_date = '2021-01-01'
>>> data_directory = 'data'
>>> bandset = catalog.create_bandset(
... paths=file_list, wavelengths=['Sentinel-2'], date=bandset_date,
... bandset_number=2, root_directory=data_directory
... )
```

Passing a directory with file name filter and the wavelength from satellite name.

```
>>> bandset = catalog.create_bandset(['directory_path', 'tif'],
→wavelengths='Sentinel-2')
```

```
create_bandset_stack(bandset_number: int | None = None, output_path: str | None = None,
                      nodata_value: int | None = None, intersection: bool = False) → str
```

Creates a raster stack of a bandset.

Stacks the raster bands of a bandset in a multiband raster.

#### Parameters

- **output\_path** – output path of the raster; if None, use temporary path.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.
- **nodata\_value** – nodata value.
- **intersection** – if True get minimum extent from input intersection, if False get maximum extent from union.

#### Returns

Path of the output raster.

#### Examples

Create BandSet 1 raster.

```
>>> catalog = BandSetCatalog()
>>> catalog.create_bandset_stack(1)
```

```
create_jpg(bandset_number: int | None = None, bands: list | None = None, output_path: str | None =
            None, quality: int = 90, nodata_value: int | None = None, intersection: bool = False) → str
```

Creates a jpg raster of a bandset.

Creates a jpg raster of a bandset.

#### Parameters

- **bandset\_number** – number of BandSet; if None, current BandSet is used.
- **bands** – list of 3 band numbers (e.g., [3, 2, 1])
- **output\_path** – output path of the jpg raster; if None, use temporary path.
- **quality** – jpg quality, default 85.
- **nodata\_value** – nodata value.
- **intersection** – if True get minimum extent from input intersection, if False get maximum extent from union.

#### Returns

Path of the output jpg file.

#### Examples

Create BandSet 1 jpg.

```
>>> catalog = BandSetCatalog()
>>> catalog.create_jpg(1)
```

**create\_virtual\_raster**(*bandset\_number*: int | None = None, *output\_path*: str | None = None, *nodata\_value*: int | None = None, *intersection*: bool = False) → str

Creates the virtual raster of a bandset.

Creates the virtual raster of a bandset.

#### Parameters

- **output\_path** – output path of the virtual raster; if None, use temporary path.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.
- **nodata\_value** – nodata value.
- **intersection** – if True get minimum extent from input intersection, if False get maximum extent from union.

#### Returns

Path of the output virtual raster.

#### Examples

Create BandSet 1 virtual raster.

```
>>> catalog = BandSetCatalog()
>>> catalog.create_virtual_raster(1)
```

**property current\_bandset: int**

Property that defines the current BandSet in the catalog.

This property identifies a BandSet number which is considered current (i.e. active) in several other tools when no BandSet is specified.

#### Returns

The integer number of current BandSet.

#### Examples

Get current BandSet.

```
>>> catalog = BandSetCatalog()
>>> bandset_number = catalog.current_bandset
>>> print(bandset_number)
1
```

Set current BandSet.

```
>>> catalog = BandSetCatalog()
>>> print(catalog.current_bandset)
1
>>> catalog.current_bandset = 2
>>> print(catalog.current_bandset)
2
```

**export\_bandset\_as\_xml**(*bandset\_number*, *output\_path*=None)

Function to export a BandSet as xml.

**find\_bandset\_names\_in\_list**(*names*: list, *lower*=True, *output\_number*=True, *exact\_match*=False) → list

Finds BandSet names.

**This function finds BandSet names in a list and return BandSets**  
or BandSet numbers.

#### Parameters

- **names** – list of string names.
- **lower** – if True, finds by lowering all the names.
- **output\_number** – if True returns the number of the band, if False returns the BandSet.
- **exact\_match** – if True, names are compared by equality.

#### Returns

if output\_number is True, returns list of band number; if output\_number is False, returns list of BandSets.

#### Examples

**Find BandSet from name list.**

```
>>> catalog = BandSetCatalog()
>>> name_list = ['name1', 'name2']
>>> bandsets = catalog.find_bandset_names_in_list(names=name_list)
```

**get\_band\_count**(*bandset\_number: None | int = None*) → None | int

Gets band count.

Gets band count of a BandSet.

#### Parameters

**bandset\_number** – number of BandSet; if None, current BandSet is used.

#### Returns

Count of bands.

#### Examples

**Get BandSet 1 band count.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_band_count(1)
```

**static get\_band\_list**(*bandset: int | list | BandSet (page 59) = None, bandset\_catalog: Optional = None*) → list

Gets band list.

This function gets band list from several types of input.

#### Parameters

- **bandset** – input of type BandSet or list of paths or integer number of BandSet.
- **bandset\_catalog** – optional type BandSetCatalog if bandset argument is a number.

#### Returns

If argument **bandset** is a **BandSet** or a **BandSet number**, returns list of bands in the **BandSet**; if argument **bandset** is already a list, returns the same list.

### Examples

Get band list of **BandSet 1**.

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> catalog = BandSetCatalog()
>>> list_1 = rs.bandset_catalog.get_band_list(1, catalog)
>>> # which is equivalent to
>>> bandset_1 = bandset_catalog.get_bandset(1)
>>> list_2 = bandset_1.get_absolute_paths()
```

**get\_bandset**(*bandset\_number: int | None = None, attribute: None | str = None*) → None | str | list | *BandSet* (page 59)

Get **BandSet** or **BandSet** attributes by number of the **BandSet**.

**This function gets the **BandSet** or **BandSet** attributes by the number of the **BandSet**.**

#### Parameters

- **bandset\_number** – number of the **BandSet**
- **attribute** – string of the attribute name, if **None** then the **BandSet** is returned

#### Returns

The **BandSet** band attributes or the **BandSet**.

### Examples

Get the ‘name’ attribute of bands of the **BandSet 1**.

```
>>> catalog = BandSetCatalog()
>>> names = catalog.get_bandset(bandset_number=1,
>>> attribute='name')
>>> print(names)
['file1', 'file2', 'file3']
```

Get the **BandSet 1**.

```
>>> catalog = BandSetCatalog()
>>> bandset_1 = catalog.get_bandset(bandset_number=1)
>>> print(bandset_1)
BandSet
```

**get\_bandset\_bands\_by\_attribute**(*bandset\_number: int, attribute: str, attribute\_value: float | int | str, output\_number: bool | None = False*) → None | list | recarray

Get **BandSet** bands from the attributes thereof.

**This function gets **BandSet** bands or the band number of bands whose attributes match an attribute value.**

**Parameters**

- **bandset\_number** – number of the BandSet
- **attribute** – string of the attribute name
- **attribute\_value** – value of the band attribute to find
- **output\_number** – if True then the output is the band number list, if False then the output is the band array

**Returns**

The band number list or the array of bands.

**Examples****Get the ‘name’ attribute of bands of the BandSet 1.**

```
>>> catalog = BandSetCatalog()
>>> band_number = catalog.get_bandset_bands_by_attribute(bandset_
→number=1, attribute='wavelength', attribute_value=0.443, output_
→number=True)
>>> print(band_number)
[2]
```

**Get the BandSet 1.**

```
>>> catalog = BandSetCatalog()
>>> band_x = catalog.get_bandset_bands_by_attribute(bandset_number=1,
→attribute='wavelength', attribute_value=0.443, output_number=True)
>>> print(band_x)
[(1, 1, '/data/file1.tif', '/data/file1.tif', 'file1', 0.443, 'µm (1
→E-6m)', ...)]
```

`get_bandset_by_name(bandset_name: str, output_number: bool | None = False) → None | int | BandSet (page 59)`

Get BandSet by name thereof.

This function gets the BandSet by the name thereof.

**Parameters**

- **bandset\_name** – name of the BandSet
- **output\_number** – if True then the output is the BandSet number, if False then the output is the BandSet

**Returns**

The BandSet identified by the name.

**Examples****Get the number of the BandSet having the name ‘example’.**

```
>>> catalog = BandSetCatalog()
>>> bandset_number = catalog.get_bandset_by_name(
bandset_name='example', output_number=True)
>>> print(bandset_number)
3
```

Get the BandSet having the name 'example'.

```
>>> catalog = BandSetCatalog()
>>> bandset = catalog.get_bandset_by_name(
bandset_name='example', output_number=False)
>>> print(bandset)
BandSet object
```

**get\_bandset\_by\_number**(*number: int*) → None | *BandSet* (page 59)

Get BandSet by number thereof.

This function gets the BandSet by the number thereof.

#### Parameters

**number** – number of the BandSet

#### Returns

The BandSet identified by the number.

#### Examples

Get the first BandSet.

```
>>> catalog = BandSetCatalog()
>>> bandset_1 = catalog.get_bandset_by_number(1)
>>> print(bandset_1)
BandSet object
```

**get\_bandset\_catalog\_attributes**(*bandset\_number: int, attribute: None | str = None*) → None | str | list

Get BandSet Catalog attributes by number of the BandSet.

This function gets the BandSet Catalog attributes by number of the BandSet.

#### Parameters

- **bandset\_number** – number of the BandSet
- **attribute** – string of the attribute name, if None then the list of attributes is returned

#### Returns

The BandSet attribute or the list of attributes

(‘bandset\_number’, ‘bandset\_name’, ‘date’, ‘root\_directory’, ‘uid’).

#### Examples

Get the ‘date’ attribute of the BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> date = catalog.get_bandset_catalog_attributes(bandset_number=1,
↳ attribute='date')
>>> print(date)
2000-12-31
```

Get the list of attributes of the BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> attributes = catalog.get_bandset_catalog_attributes(bandset_
→number=1)
>>> print(attributes)
[(1, 'example', '2000-12-31', 'None', '20000101_1605495327_293')]
```

**get\_bandset\_count()** → int

Gets count of BandSets in the catalog.

This function gets the count of BandSets present in the catalog.

**Returns**

The integer number of BandSets.

**Examples**

**Count of BandSets present.**

```
>>> catalog = BandSetCatalog()
>>> count = catalog.get_bandset_count()
>>> print(count)
1
```

**get\_bandsets\_by\_date()** (*date\_list: list, output\_number: bool | None = False*) → list

Get BandSets by date.

This function gets the BandSets by date.

**Parameters**

- **date\_list** – list of date strings, or single date string (format YYYY-MM-DD); it can also include ranges using > or <, multiple conditions including &
- **output\_number** – if True then the output is the BandSet number, if False then the output is the BandSet

**Returns**

The BandSet identified by the name.

**Examples**

**Get the number of the BandSet by date.**

```
>>> catalog = BandSetCatalog()
>>> bandset_number = catalog.get_bandsets_by_date(date_list=['2020-
→01-01'], output_number=True)
>>> print(bandset_number)
[1]
```

**Get the number of the BandSet by range of dates.**

```
>>> catalog = BandSetCatalog()
>>> bandset_number = catalog.get_bandsets_by_date(date_list=['2020-
→01-01', '>=2021-01-01 & <=2022-01-02'], output_number=True)
>>> print(bandset_number)
[1, 3]
```

**get\_bandsets\_by\_list**(*bandset\_list*: list | None = None, *output\_number*: bool | None = False) → list

Gets BandSets by list.

This function gets all the BandSets in the Catalog or filtered using a list of BandSet numbers.

#### Parameters

- **bandset\_list** – list of integers BandSet numbers.
- **output\_number** – if True, returns the list of BandSet number; if False, returns the list of BandSet object.

#### Returns

List of BandSets, or list of BandSets numbers if *output\_number* is True.

#### Examples

##### Get BandSets.

```
>>> catalog = BandSetCatalog()
>>> bandset_t = catalog.get_bandsets_by_list()
>>> for bandset in bandset_t:
>>>     print(bandset)
```

**get\_bbox**(*bandset\_number*: int | None = None) → None | list

Get BandSet bounding box.

This function gets the bounding box coordinates of a BandSet.

#### Parameters

**bandset\_number** – number of the BandSet

#### Returns

The bounding box coordinates [left, top, right, bottom].

#### Examples

##### Get the bounding box of the BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> names = catalog.get_bandset(bandset_number=1)
>>> print(names)
['file1', 'file2', 'file3']
```

##### Get the BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> bandset_1 = catalog.get_bandset(bandset_number=1)
>>> print(bandset_1)
BandSet
```

**get\_box\_coordinate\_list**(*bandset\_number*: int | None = None) → None | list

Gets BandSet box coordinate list.

Gets BandSet box coordinate list.

#### Parameters

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Returns**

List of box coordinates [left, top, right, bottom].

**Examples****Get BandSet 1 band count.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_box_coordinate_list(1)
```

**get\_crs**(*bandset\_number*: None | int = None)

Gets BandSet crs.

Gets BandSet crs from Bandset information.

**Parameters**

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples****Get BandSet 1 crs.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_crs(bandset_number=1)
```

**get\_date**(*bandset\_number*: None | int = None) → str

Gets BandSet date.

Gets BandSet date.

**Parameters**

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Returns**

Date string.

**Examples****Get BandSet 1 date.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_date(1)
```

**get\_name**(*bandset\_number*: None | int = None) → str

Gets BandSet name.

Gets BandSet name.

**Parameters**

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Returns**

BandSet name.

**i** Examples**Get BandSet 1 date.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_name(1)
```

**get\_root\_directory**(*bandset\_number: None | int = None*) → str

Gets BandSet root directory.

Gets BandSet root directory.

**Parameters****bandset\_number** – number of BandSet; if None, current BandSet is used.**Returns**

Root directory string.

**i** Examples**Get BandSet 1 root directory.**

```
>>> catalog = BandSetCatalog()
>>> catalog.get_root_directory(1)
```

**import\_bandset\_from\_xml**(*bandset\_number, xml\_path*)

Function to import a BandSet from xml.

**iterate\_bandset\_bands**(*attribute: str*) → list

Iterates BandSet attributes.

**This function gets BandSet attributes iterating all the BandSets in the Catalog.****Parameters****attribute** – attribute name.**Returns**

List of attributes

**i** Examples**Get BandSet names.**

```
>>> catalog = BandSetCatalog()
>>> names = catalog.iterate_bandset_bands('name')
```

**move\_band\_in\_bandset**(*band\_number\_input: int, band\_number\_output: int, bandset\_number: None | int = None, wavelength=True*)

Moves band in Bandset.

This function reorders a band in a Bandset.

**Parameters**

- **band\_number\_input** – number of band to be moved.

- **band\_number\_output** – position of the moved band.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.
- **wavelength** – if True, keep the wavelength attributes of the band order.

#### Examples

Move the second band of the BandSet 1 to position 5.

```
>>> catalog = BandSetCatalog()
>>> catalog.move_band_in_bandset(
... bandset_number=1, band_number_input=2, band_number_output=5
... )
```

**move\_bandset**(*bandset\_number\_input: int, bandset\_number\_output: int*)

Moves a BandSet.

This function reorders a BandSet in the BandSet Catalog.

#### Parameters

- **bandset\_number\_input** – the BandSet number to be moved.
- **bandset\_number\_output** – the new position of BandSet.

#### Examples

Move BandSet 1 to position 3.

```
>>> catalog = BandSetCatalog()
>>> catalog.move_bandset(bandset_number_input=1, bandset_number_
→output=3)
```

**print\_bandset**(*bandset\_number=None*)

Function to print a BandSet bands and attributes.

**remove\_band\_in\_bandset**(*band\_number: int, bandset\_number: None | int = None*)

Removes band in Bandset.

This function removes a band in Bandset identified by a number. Automatically reorders other band numbers.

#### Parameters

- **band\_number** – number of band to be removed.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

#### Examples

Remove the second band of the BandSet.

```
>>> catalog = BandSetCatalog()
>>> catalog.remove_band_in_bandset(
... bandset_number=1, band_number=2
... )
```

**remove\_bandset**(*bandset\_number: int*)

Removes a BandSet.

This function removes a BandSet by the number thereof.

**Parameters**

**bandset\_number** – the BandSet number to be removed.

**Examples**

**Remove BandSet 2.**

```
>>> catalog = BandSetCatalog()
>>> catalog.remove_bandset(2)
```

**reset**()

Resets the BandSets Catalog.

**This function resets the BandSets Catalog removing all BandSets and creating an empty one.**

**Examples**

**Reset the BandSets catalog.**

```
>>> catalog = BandSetCatalog()
>>> catalog.reset()
```

**set\_box\_coordinate\_list**(*box\_coordinate\_list: list, bandset\_number: None | int = None*)

Sets BandSet box coordinate list.

Sets BandSet box coordinate list for virtual subset.

**Parameters**

- **box\_coordinate\_list** – list of coordinates [left, top, right, bottom] to create a virtual subset.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples**

**Set BandSet 1 coordinate list.**

```
>>> catalog = BandSetCatalog()
>>> catalog.set_box_coordinate_list(
...   bandset_number=1, box_coordinate_list=[230000, 4680000, 232000,
...   ↪4670000]
... )
```

**set\_crs**(*crs: str, bandset\_number: None | int = None*)

Sets BandSet crs.

Sets BandSet crs from Bandset information.

**Parameters**

- **crs** – crs string.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

#### Examples

##### Set BandSet 1 crs.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_crs(bandset_number=1, crs='PROJCS["WGS 84 / UTM zone_
→33N"...']')
```

**set\_date**(date: str, bandset\_number: None | int = None)

Sets BandSet date.

Sets BandSet date.

#### Parameters

- **date** – date string (format YYYY-MM-DD).
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

#### Examples

##### Set BandSet 1 date.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_date(bandset_number=1, date='2021-01-01')
```

**set\_name**(name: str, bandset\_number: int | None = None)

Sets BandSet name.

Sets BandSet name.

#### Parameters

- **name** – name.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

#### Examples

##### Set BandSet 1 name.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_name(bandset_number=1, name='example')
```

**set\_paths**(path\_list, bandset\_number=None)

Sets BandSet band path.

Sets BandSet band path based on list of paths.

#### Parameters

- **path\_list** – list of string paths.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples**

Set BandSet 1 satellite wavelengths.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_satellite_wavelength(
...   bandset_number=1, path_list=['path_1', 'path_2']
... )
```

**set\_root\_directory**(*root\_directory: str, bandset\_number: None | int = None*)

Sets BandSet root directory.

Sets BandSet root directory for relative path.

**Parameters**

- **root\_directory** – root directory path.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples**

Set BandSet 1 root directory.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_root_directory(bandset_number=1, root_directory=
→ 'data_directory')
```

**set\_satellite\_wavelength**(*satellite\_name, bandset\_number=None*)

Sets BandSet center wavelength based on satellite.

Sets BandSet center wavelength based on satellite name.

**Parameters**

- **satellite\_name** – name of satellite (e.g., Landsat 8)
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples**

Set BandSet 1 satellite wavelengths.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_satellite_wavelength(
...   bandset_number=1, satellite_name='Sentinel-2'
... )
```

**set\_wavelength**(*wavelength\_list, unit, bandset\_number=None*)

Sets BandSet center wavelength based on list.

Sets BandSet center wavelength based on list.

**Parameters**

- **wavelength\_list** – list of wavelength values.
- **bandset\_number** – number of BandSet; if None, current BandSet is used.

- **unit** – wavelength unit.

#### **i** Examples

Set BandSet 1 satellite wavelengths.

```
>>> catalog = BandSetCatalog()
>>> catalog.set_satellite_wavelength(
... bandset_number=1, wavelength_list=[1, 2, 3], unit='μm (1 E-6m)'
... )
```

**sort\_bands\_by\_name**(*bandset\_number: None | int = None, keep\_wavelength\_order: bool | None = True*)

Sorts bands by name.

This function numerically sorts bands in a BandSet by name.

#### Parameters

- **bandset\_number** – number of BandSet; if None, current BandSet is used.
- **keep\_wavelength\_order** – if True, keep wavelength\_order.

#### **i** Examples

Sort bands in BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> catalog.sort_bands_by_name(bandset_number=1)
```

**sort\_bands\_by\_wavelength**(*bandset\_number: None | int = None*)

Sorts bands by wavelength.

This function numerically sorts bands in a BandSet by wavelength center.

#### Parameters

**bandset\_number** – number of BandSet; if None, current BandSet is used.

#### **i** Examples

Sort bands in BandSet 1.

```
>>> catalog = BandSetCatalog()
>>> catalog.sort_bands_by_wavelength(bandset_number=1)
```

**sort\_bandsets\_by\_date**()

Sort BandSets by BandSet date.

This function sorts BandSets in the BandSet Catalog based on the date.

#### **i** Examples

Sort BandSets.

```
>>> catalog = BandSetCatalog()
>>> catalog.sort_bandsets_by_date()
```

**update\_crs**(*bandset\_number: None | int = None*)

Updates BandSet crs.

Updates BandSet crs from Bandset first band.

**Parameters**

**bandset\_number** – number of BandSet; if None, current BandSet is used.

**Examples**

Update BandSet 1 crs.

```
>>> catalog = BandSetCatalog()
>>> catalog.update_crs(bandset_number=1)
```

### remotior\_sensus.core.configurations module

Configuration module. Module containing shared variables and parameters across tools.

remotior\_sensus.core.configurations.multiprocess: [Multiprocess](#) (page 92)

### remotior\_sensus.core.log module

Logging manger.

Core class that manages logs during processes.

Typical usage example:

```
>>> # create a log file in a directory
>>> Log(directory='directory_path', level=10)
```

```
class remotior_sensus.core.log.Log(file_path: None | str = None, directory: None | str = None, level:
    int | str | None = None, multiprocess=False, time=True,
    stream_handler=True)
```

Bases: object

```
__init__(file_path: None | str = None, directory: None | str = None, level: int | str | None = None,
    multiprocess=False, time=True, stream_handler=True)
```

Manages logs.

This module allows for managing logs of processes.

**file\_path**

path of a log file.

**directory**

directory path where a log file is created if file\_path is None.

**level**

level of logging (10 for DEBUG, 20 for INFO).

**multiprocess**

if True, sets logging for parallel processes.

**time**

if True, time is saved in log file.

**stream\_handler**

if True, create stream handler.

**Examples**

Create a log file and starts logging.

```
>>> Log(file_path='file.txt', level=20)
```

**log = None**

**set\_level**(*level*)

**remotior\_sensus.core.messages module**

Manager of messages.

Console messages during processes.

Typical usage example:

```
>>> # display a warning message
>>> warning('warning message')
```

**remotior\_sensus.core.messages.error**(*message: str*)

Error message.

Prints an error message.

**Parameters**

**message** – message.

**Examples**

Display a message

```
>>> error('error message')
```

**remotior\_sensus.core.messages.info**(*message: str*)

Info message.

Prints an info message.

**Parameters**

**message** – message.

**Examples**

Display a message

```
>>> info('error message')
```

`remotior_sensus.core.messages.warning(message: str)`

Warning message.

Prints a warning message.

#### Parameters

**message** – message.

#### Examples

##### Display a message

```
>>> warning('warning message')
```

## remotior\_sensus.core.multiprocess\_manager module

`class remotior_sensus.core.multiprocess_manager.Multiprocess(n_processes: int | None = None, multiprocessing_module=None)`

Bases: object

`__init__(n_processes: int | None = None, multiprocessing_module=None)`

`create_warped_vrt(raster_path, output_path, output_wkt=None, align_raster_path=None, same_extent=False, n_processes: int | None = None, src_nodata=None, dst_nodata=None, extra_params=None)`

`find_minimum_dn()`

`find_minimum_maximum()`

`gdal_copy_raster(input_raster, output, output_format='GTiff', compress=None, compress_format='DEFLATE', additional_params="", n_processes=1, available_ram: int | None = None, min_progress=None, max_progress=None)`

`gdal_warping(input_raster, output, output_format='GTiff', s_srs=None, t_srs=None, resample_method=None, raster_data_type=None, compression=None, compress_format='DEFLATE', additional_params="", n_processes: int | None = None, available_ram: int | None = None, src_nodata=None, dst_nodata=None, min_progress=None, max_progress=None)`

`get_dictionary_sum()`

`join_tables_multiprocess(table1, table2, field1_name, field2_name, nodata_value=None, join_type=None, postfix=None, n_processes: int | None = None, progress_message=None, min_progress=None, max_progress=None)`

#### Parameters

- **table1** – input numpy table 1
- **table2** – input numpy table 2
- **field1\_name** – input field table 1
- **field2\_name** – input field table 2
- **nodata\_value** – input nodata value
- **join\_type** – join type
- **postfix** – postfix string
- **n\_processes** – number of parallel processes.

- **progress\_message** – progress message
- **min\_progress** – minimum progress value
- **max\_progress** – maximum progress value

**multi\_download\_file**(*url\_list, output\_path\_list, authentication\_uri=None, user=None, password=None, proxy\_host=None, proxy\_port=None, proxy\_user=None, proxy\_password=None, progress=None, message=None, min\_progress=0, max\_progress=100, retried=False, timeout=20, copernicus=False, access\_token=None, ignore\_errors=True*)

**multiprocess\_pixel\_value**()

**multiprocess\_raster\_sieve**(*raster\_path, n\_processes: int | None = None, sieve\_size=None, connected=None, output\_nodata\_value=None, output=None, output\_data\_type=None, compress=None, compress\_format=None, available\_ram: int | None = None, min\_progress=0, max\_progress=100*)

**multiprocess\_raster\_to\_vector**(*raster\_path, output\_vector\_path, field\_name=None, n\_processes: int | None = None, dissolve\_output=False, min\_progress=0, max\_progress=100, available\_ram: int | None = None*)

**multiprocess\_raster\_to\_vector\_old**(*raster\_path, output\_vector\_path, field\_name=None, n\_processes: int | None = None, dissolve\_output=True, min\_progress=0, max\_progress=100, available\_ram: int | None = None*)

**multiprocess\_region\_growing**()

**multiprocess\_roi\_arrays**()

**multiprocess\_scatter\_values**()

#### Parameters

- **device** – processing device ‘cpu’ or ‘cuda’ if available.

- **classification\_confidence** – if True, write also additional classification confidence rasters as output.
- **signature\_raster** – if True, write additional rasters for each spectral signature as output.
- **raster\_path** – input path.
- **multi\_add\_factors** – list of multiplicative and additive factors.
- **virtual\_raster** – if True, create virtual raster output.
- **offset** – integer number of output offset.
- **scale** – integer number of output scale.
- **delete\_array** – if True delete output array.
- **keep\_output\_argument** – if True keep output argument for post processing.
- **keep\_output\_array** – if True keep output array for post processing.
- **unique\_section** – if True consider the whole raster as unique section.
- **dummy\_bands** – integer number of dummy bands to be counted for calculating block size
- **available\_ram** – integer value of RAM in MB.
- **any\_nodata\_mask** – True to apply the nodata where any input is nodata, False to apply nodata where all inputs are nodata, None not apply nodata
- **input\_nodata\_as\_value** – consider nodata as value in calculation
- **output\_data\_type** – string of data type for output raster such as Float32 or Int16
- **output\_band\_number** – number of bands of the output
- **output\_nodata\_value** – output nodata value
- **compress\_format** – string of format of raster compression
- **compress** – True to compress the output raster or False not to compress
- **boundary\_size** – integer number of pixels used to extend the boundary of calculations
- **output\_raster\_path** – list of output path strings
- **calculation\_datatype** – datatype use during calculation
- **function\_variable** – list of variables for function
- **function\_argument** – arguments of function
- **n\_processes** – number of parallel processes.
- **function** – function name
- **specific\_output** – dictionary of values for specific output raster
- **classification** – if True, settings are defined for a classification output
- **use\_value\_as\_nodata** – integer value as nodata in calculation
- **separate\_bands** – if True, calculate a section for each raster range
- **progress\_message** – progress message
- **multiple\_block** – allows for setting block size as a multiple of the pixel count here defined
- **min\_progress** – minimum progress value
- **max\_progress** – maximum progress value

**run\_iterative\_process**(*function\_list*, *argument\_list*, *min\_progress=None*, *max\_progress=None*, *n\_processes=None*)

- **n\_processes** – number of parallel processes.
- **function** – function name
- **raster\_path\_list** – input path
- **use\_value\_as\_nodata** – list of integer values as nodata in calculation
- **progress\_message** – progress message
- **min\_progress** – minimum progress value
- **max\_progress** – maximum progress value

```
start(n_processes, multiprocess_module=None)

stop()
```

### remotior\_sensus.core.output\_manager module

Output manager.

Core class that manages several types of output, mainly intended for tools that have several outputs.

Typical usage example:

```
>>> # process output is checked
>>> OutputManager()
```

```
class remotior_sensus.core.output_manager.OutputManager(check: bool = True, path: str | None = None, paths: list | None = None, extra=None)
```

Bases: object

Manages output.

This class manages several types of output, mainly intended for tools that have several outputs. Check argument is False if output failed. Single output raster or multiple file paths can be defined as arguments. Additional output files or tables are managed with an extra argument. The type of the extra argument can be flexible depending on the process output.

#### check

True if output is as expected, False if process failed.

#### path

path of the first output.

#### paths

list of output paths in case of multiple outputs.

#### extra

additional output elements depending on the process.

### Examples

#### Output failed

```
>>> OutputManager(check=False)
```

#### Output is checked and file path is provided

```
>>> OutputManager(path='file.tif')
```

```
__init__(check: bool = True, path: str | None = None, paths: list | None = None, extra=None)
```

Initializes an Output.

Initializes an Output.

#### Parameters

- **check** – True if output is as expected, False if process failed.
- **path** – path of the first output.
- **paths** – list of output paths in case of multiple outputs.

- **extra** – additional output elements depending on the process.

### Examples

#### Create an object with a single file path

```
>>> OutputManager(path='file.tif')
```

#### Create an object with several output file paths in a list and an extra argument for a dictionary

```
>>> OutputManager(
... paths=['file1.tif', 'file2.tif'],
... extra={'additional_output': 'file.csv'}
... )
```

)

**add\_to\_bandset**(*bandset\_catalog*: [BandSetCatalog](#) (page 70), *bandset\_number*=None, *band\_number*=None, *raster\_band*=None, *band\_name*=None, *date*=None, *unit*=None, *root\_directory*=None, *multiplicative\_factor*=None, *additive\_factor*=None, *wavelength*=None)

Adds output to BandSet.

Adds the OutputManager.path as a band to a BandSet in a BandSetCatalog.

#### Parameters

- **bandset\_catalog** – BandSetCatalog object.
- **band\_name** – raster name used for identifying the bands.
- **wavelength** – center wavelengths of band.
- **unit** – wavelength unit as string
- **multiplicative\_factor** – multiplicative factor for bands during calculations.
- **additive\_factor** – additive factors for band during calculations.
- **date** – date string (format YYYY-MM-DD).
- **bandset\_number** – number of the BandSet; if None, the band is added to the current BandSet.
- **root\_directory** – root directory for relative path.
- **raster\_band** – raster band number.
- **band\_number** – number of band in BandSet.

### Examples

#### Add the output to BandSet 1 as band 1.

```
>>> catalog = BandSetCatalog()
>>> OutputManager.add_to_bandset(
... bandset_catalog=catalog, bandset_number=1, band_number=1
... )
```

**remotior\_sensus.core.processor module**

```
class remotior_sensus.core.processor.RasterPiece(section_list, x_min, y_min, x_max, y_max,  
x_size, y_size, y_min_no_boundary=None,  
y_max_no_boundary=None,  
y_size_boundary_top=None,  
y_size_boundary_bottom=None,  
y_size_no_boundary=None)
```

Bases: object

```
__init__(section_list, x_min, y_min, x_max, y_max, x_size, y_size, y_min_no_boundary=None,  
y_max_no_boundary=None, y_size_boundary_top=None, y_size_boundary_bottom=None,  
y_size_no_boundary=None)
```

**Parameters**

- **section\_list** – list of sections
- **x\_min** – left position
- **y\_min** – top position
- **x\_max** – right position
- **y\_max** – bottom position
- **x\_size** – piece x size
- **y\_size** – piece y size
- **y\_min\_no\_boundary** – top position without boundary
- **y\_max\_no\_boundary** – bottom position without boundary
- **y\_size\_boundary\_top** – top pixel buffer
- **y\_size\_boundary\_bottom** – bottom pixel buffer
- **y\_size\_no\_boundary** – piece size without buffer

**y\_details**()

```
class remotior_sensus.core.processor.RasterSection(x_min, y_min, x_max, y_max, x_size, y_size,  
y_min_no_boundary=None,  
y_max_no_boundary=None,  
y_size_boundary_top=None,  
y_size_boundary_bottom=None,  
y_size_no_boundary=None)
```

Bases: object

```
__init__(x_min, y_min, x_max, y_max, x_size, y_size, y_min_no_boundary=None,  
y_max_no_boundary=None, y_size_boundary_top=None, y_size_boundary_bottom=None,  
y_size_no_boundary=None)
```

**Parameters**

- **x\_min** – left position
- **y\_min** – top position
- **x\_max** – right position
- **y\_max** – bottom position
- **x\_size** – section x size
- **y\_size** – section y size
- **y\_min\_no\_boundary** – top position without boundary

- **y\_max\_no\_boundary** – bottom position without boundary
- **y\_size\_boundary\_top** – top pixel buffer
- **y\_size\_boundary\_bottom** – bottom pixel buffer
- **y\_size\_no\_boundary** – section size without buffer

## remotior\_sensus.core.session module

Session manager.

Core class that manages the Remotior Sensus' session. It defines fundamental parameters such as available RAM and number of parallel processes. Creates a temporary directory to store temporary files. Exposes core functions and tools. It includes a method to close the session removing temporary files and stopping parallel processes.

Typical usage example:

```
>>> # start the session
>>> rs = Session()
>>> # optionally set session parameters
>>> rs.set(n_processes=2)
>>> # close the session when processing is done
>>> rs.close()
```

```
class remotior_sensus.core.session.Session(n_processes: int | None = 2, available_ram: int = 2048,
                                           temporary_directory: str | None = None,
                                           directory_prefix: str | None = None, log_level: int = 20,
                                           log_time: bool = True, progress_callback=None,
                                           multiprocessing_module=None, messages_callback=None,
                                           smtp_server=None, smtp_user=None,
                                           smtp_password=None, smtp_recipients=None,
                                           smtp_notification=None, sound_notification=None,
                                           log_stream_handler=True)
```

starts a Jupyter interface

**Examples**

**Start a session**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
```

**Start a session defining number of parallel processes. and available RAM**

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session(n_processes=4,available_ram=4096)
```

**Create a `BandSetCatalog()` (page 70)**

```
>>> catalog = rs.bandset_catalog()
```

**Run the tool for raster report**

```
>>> output = rs.raster_report(raster_path='file.tif', output_path=
↳ 'output.txt')
```

**Start an interactive Jupyter interface**

```
>>> rs.jupyter().download_interface()
```

**Stop a session at the end to clear temporary directory**

```
>>> rs.close()
```

```
__init__(n_processes: int | None = 2, available_ram: int = 2048, temporary_directory: str | None =
None, directory_prefix: str | None = None, log_level: int = 20, log_time: bool = True,
progress_callback=None, multiprocessing_module=None, messages_callback=None,
smtp_server=None, smtp_user=None, smtp_password=None, smtp_recipients=None,
smtp_notification=None, sound_notification=None, log_stream_handler=True)
```

Starts a session.

Starts a new session setting fundamental parameters for processing. It sets the number of parallel processes (default 2) and available RAM (default 2048MB) to be used in calculations. It starts the class Temporary to manage temporary files by creating a temporary directory with an optional name

prefix. It starts the class Log for logging (with a default level INFO) and creates a logging formatter with the option to hide time. It starts the class Progress for displaying progress with a default callback function. A custom progress callback function can be passed optionally.

The sessions also allows for accessing to the core functions and tools.

In the end, the close() function should be called to clear the temporary directory and stop the parallel processes.

#### Parameters

- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **temporary\_directory** – path to a temporary directory.
- **directory\_prefix** – prefix of the name of the temporary directory.
- **log\_level** – level of logging (10 for DEBUG, 20 for INFO).
- **log\_time** – if True, logging includes the time.
- **progress\_callback** – function for progress callback.
- **multiprocess\_module** – multiprocessing module, useful if Remotior Sensus' session is started from another Python module.
- **messages\_callback** – message module, useful if Remotior Sensus' session is started from another Python module.
- **smtp\_server** – optional server for SMTP notification.
- **smtp\_user** – user for SMTP authentication.
- **smtp\_password** – password for SMTP authentication.
- **smtp\_recipients** – string of one or more email addresses separated by comma for SMTP notification.
- **smtp\_notification** – optional, if True send SMTP notification.
- **sound\_notification** – optional, if True play sound notification.
- **log\_stream\_handler** – optional, if True create stream handler.

#### Examples

##### Start a session

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
```

**close**(log\_path: str | None = None)

Closes a Session.

This function closes current session by deleting the temporary files and stopping parallel processes.

#### Parameters

**log\_path** – path where the log file is saved

#### Examples

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
```

Set the number of parallel processes and available RAM

```
>>> rs.set(n_processes=8, available_ram=20480)
```

Set the logging level to DEBUG

```
>>> rs.set(log_level=10)
```

**set**(*n\_processes*: int | None = None, *available\_ram*: int | None = None, *temporary\_directory*: str | None = None, *directory\_prefix*: str | None = None, *log\_level*: int | None = None, *log\_time*: bool | None = None, *progress\_callback*: LambdaType | None = None, *smtp\_server*=None, *smtp\_user*=None, *smtp\_password*=None, *smtp\_recipients*=None, *sound\_notification*=None, *smtp\_notification*=None, *log\_stream\_handler*=True)

Sets or changes the parameters of an existing Session.

Sets the parameters of an existing Session such as number of processes or temporary directory.

#### Parameters

- **n\_processes** – number of parallel processes.
- **available\_ram** – number of megabytes of RAM available to processes.
- **temporary\_directory** – path to a temporary directory.
- **directory\_prefix** – prefix of the name of the temporary directory.
- **log\_level** – level of logging (10 for DEBUG, 20 for INFO).
- **log\_time** – if True, logging includes the time.
- **progress\_callback** – function for progress callback.
- **smtp\_server** – optional server for SMTP notification.
- **smtp\_user** – user for SMTP authentication.
- **smtp\_password** – password for SMTP authentication.
- **smtp\_recipients** – string of one or more email addresses separated by comma for SMTP notification.
- **smtp\_notification** – optional, if True send SMTP notification.
- **sound\_notification** – optional, if True play sound notification.
- **log\_stream\_handler** – optional, if True create stream handler.

#### Examples

Given that a session was previously started

```
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
```

Stop a session

```
>>> rs.close()
```

Stop a session saving also the log to a file

```
>>> rs.close(log_path='file.txt')
```

### remotior\_sensus.core.spectral\_signatures module

```
class remotior_sensus.core.spectral_signatures.SpectralSignaturePlot(value, wavelength,
                                                                    stan-
                                                                    dard_deviation=None,
                                                                    pixel_count=None,
                                                                    signature_id=None,
                                                                    macroclass_id=None,
                                                                    class_id=None,
                                                                    macro-
                                                                    class_name=None,
                                                                    class_name=None,
                                                                    color_string=None,
                                                                    selected=None)
```

Bases: object

A class to manage Spectral Signatures for plots.

```
__init__(value, wavelength, standard_deviation=None, pixel_count=None, signature_id=None,
          macroclass_id=None, class_id=None, macroclass_name=None, class_name=None,
          color_string=None, selected=None)
```

```
class remotior_sensus.core.spectral_signatures.SpectralSignaturePlotCatalog(signature:
                                                                              SpectralSig-
                                                                              naturePlot
                                                                              (page 107) |
                                                                              None =
                                                                              None)
```

Bases: object

A class to manage Spectral Signatures Catalog for plots.

```
__init__(signature: SpectralSignaturePlot (page 107) | None = None)
```

```
add_signature(signature: SpectralSignaturePlot (page 107))
```

```
get_generic_attributes(selected=True) → list
```

Gets generic attributes in the catalog.

This function gets generic attributes from the catalog.

#### Returns

The list of values.

```
get_signature(signature_id) → SpectralSignaturePlot (page 107)
```

Gets signature in the catalog.

This function gets signature by id from the catalog.

#### Returns

The SpectralSignaturePlot.

### Examples

**Get signature.**

```
>>> catalog = SpectralSignaturePlotCatalog()
>>> signature = catalog.get_signature(signature_id='signature_id')
>>> print(signature.signature_id)
'signature_id'
```

**get\_signature\_color**(*selected=True*) → list

Gets signature color in the catalog.

This function gets signature color from the catalog.

**Returns**

The list of values.

**get\_signature\_count**() → int

Gets count of signatures in the catalog.

This function gets the count of signatures present in the catalog.

**Returns**

The integer number of signatures.

### Examples

**Count of signatures present.**

```
>>> catalog = SpectralSignaturePlotCatalog()
>>> count = catalog.get_signature_count()
>>> print(count)
1
```

**get\_signature\_ids**() → list

Gets signature ids in the catalog.

This function gets signature ids from the catalog.

**Returns**

The list of ids.

### Examples

**Get signature.**

```
>>> catalog = SpectralSignaturePlotCatalog()
>>> signature_ids = catalog.get_signature_ids()
>>> print(signature_ids)
['signature_id']
```

**get\_signature\_names**(*selected=True*) → list

Gets signature names in the catalog.

This function gets signature names from the catalog, derived from SpectralSignaturePlot.

**Returns**

The list of values.

**Examples****Get signature.**

```
>>> catalog = SpectralSignaturePlotCatalog()
>>> signature_names = catalog.get_signature_names()
>>> print(signature_names)
['name ']
```

**get\_signature\_standard\_deviation**(*selected=True*) → list

Gets signature standard deviation in the catalog.

This function gets signature standard deviation from the catalog.

**Returns**

The list of values.

**get\_signature\_values**(*selected=True*) → list

Gets signature values in the catalog.

This function gets signature values from the catalog.

**Returns**

The list of values.

**get\_signature\_wavelength**(*selected=True*) → list

Gets signature wavelength in the catalog.

This function gets signature wavelength from the catalog.

**Returns**

The list of values.

**remove\_signature**(*signature\_id: str*)

```
class remotior_sensus.core.spectral_signatures.SpectralSignaturesCatalog(bandset: BandSet (page 59) | None = None, catalog_table=None, geometry_file_path=None, macroclass_field=None, class_field=None)
```

Bases: object

A class to manage Spectral Signatures and ROIs.

```
__init__(bandset: BandSet (page 59) | None = None, catalog_table=None, geometry_file_path=None, macroclass_field=None, class_field=None)
```

```
add_signatures_to_plot_by_id(signature_id_list, return_plot=False)
```

```
add_spectral_signature(value_list, macroclass_id=None, class_id=None, macroclass_name=None, class_name=None, wavelength_list=None, standard_deviation_list=None, signature_id=None, selected=1, min_dist_thr=0, max_like_thr=0, spec_angle_thr=0, geometry=0, signature=0, color_string=None, pixel_count=0, unit=None)
```

Adds a spectral signature.

This method adds spectral signature to Spectral Signatures Catalog.

**Parameters**

- **value\_list**
- **macroclass\_id**
- **class\_id**
- **macroclass\_name**
- **class\_name**
- **wavelength\_list**
- **standard\_deviation\_list**
- **signature\_id**
- **selected**
- **min\_dist\_thr**
- **max\_like\_thr**
- **spec\_angle\_thr**
- **geometry**
- **signature**
- **color\_string**
- **pixel\_count** – pixel count
- **unit** – unit

**Returns**

object *OutputManager()* (page 96)

```

```
remotior_sensus.core.spectral_signatures.generate_signature_id()
```

### remotior\_sensus.core.table\_manager module

Table manager.

This tool allows for managing table data as NumPy structured arrays. It includes functions for field calculation, join and pivot tables. Also, functions to manage tables used in other tools are included. Tables can be exported to csv files.

Typical usage example:

```
>>> # import Remotior Sensus and start the session
>>> import remotior_sensus
>>> rs = remotior_sensus.Session()
>>> # open a file
>>> file1 = 'file1.csv'
>>> table1 = rs.table_manager.open_file('file1.csv', field_names=['field1', 'field2'])
>>> # perform a calculation
>>> calculation = rs.table_manager.calculate(
... matrix=table1, expression_string='"field1" * 1.5',
... output_field_name='calc'
... )
>>> # export the table to csv
>>> rs.table_manager.export_table(
... matrix=calculation, output_path='output.csv',
... fields=['field1', 'calc'], separator=';', decimal_separator='.'
... )
```

```
remotior_sensus.core.table_manager.add_product_to_preprocess(product_list, spacecraft_list,
                                                            processing_level,
                                                            band_name_list,
                                                            product_path_list, scale_list,
                                                            offset_list, nodata_list, date_list,
                                                            k1_list, k2_list,
                                                            band_number_list, e_sun_list,
                                                            sun_elevation_list,
                                                            earth_sun_distance_list)
```

```
remotior_sensus.core.table_manager.add_spectral_signature_to_catalog_table(signature_id=None,
                                                                           macro-
                                                                           class_id=0,
                                                                           class_id=0,
                                                                           class_name=None,
                                                                           previ-
                                                                           ous_catalog=None,
                                                                           selected=1,
                                                                           min_dist_thr=0,
                                                                           max_like_thr=0,
                                                                           spec_angle_thr=0,
                                                                           geometry=0,
                                                                           signature=0,
                                                                           color_string=None,
                                                                           pixel_count=0,
                                                                           unit=None)
```

```
remotior_sensus.core.table_manager.append_field(matrix, field_name, data, data_type)
```

```
remotior_sensus.core.table_manager.append_tables(matrix1, matrix2)
```

```
remotior_sensus.core.table_manager.append_values_to_table(matrix, value_list)

remotior_sensus.core.table_manager.calculate(matrix, expression_string, output_field_name,
                                             progress_message=True)
```

#### Parameters

- **matrix** – input matrix
- **expression\_string** – string used for calculation where fields must be named using double quotes e.g.”field\_name” or using ‘field.’ such as field.field\_name or ‘matrix.’ such as matrix.field\_name
- **output\_field\_name** – string of output field name
- **progress\_message** – optional, if True display process message

```
remotior_sensus.core.table_manager.calculate_multi(matrix, expression_string_list,
                                                  output_field_name_list,
                                                  progress_message=True)
```

#### Parameters

- **matrix** – input matrix
- **expression\_string\_list** – list of strings used for calculation where fields must be named using double quotes e.g.”field\_name” or using ‘field.’ such as field.field\_name or ‘matrix.’ such as matrix.field\_name
- **output\_field\_name\_list** – list of strings of output field names
- **progress\_message** – optional, if True display process message

```
remotior_sensus.core.table_manager.columns(matrix)
```

```
remotior_sensus.core.table_manager.create_band_table(band_number=0, raster_band=None,

```
remotior_sensus.core.table_manager.export_table(matrix, output_path, fields=None, field_decimals:
int | list = 2, separator=None,
decimal_separator=None, nodata_value=None,
nodata_value_output='nan',
progress_message=True)
```

#### Parameters

- **matrix** – input matrix
- **output\_path** – output path
- **fields** – optional list of fields to export
- **field\_decimals** – integer number of decimals for decimal fields or list of integer values for decimal fields
- **separator** – separator of fields
- **decimal\_separator** – optional decimal separator for float values replacing . character

- **nodata\_value** – optional nodata value to be replaced
- **nodata\_value\_output** – optional string to replace nodata value in output
- **progress\_message**

`remotior_sensus.core.table_manager.find_nearest_value(array, field_name, value, threshold=None)`

`remotior_sensus.core.table_manager.get_values(matrix, value_field, conditional_string=None, progress_message=True)`

#### Parameters

- **matrix** – input matrix
- **value\_field** – string of value field name
- **conditional\_string** – optional string used for condition where field must be referred to using ‘field.’ such as `field.field_name` or ‘matrix.’ such as `matrix.field_name`
- **progress\_message** – optional, if True display process message

`remotior_sensus.core.table_manager.join_matrices(matrix1, matrix2, field1_name, field2_name, join_type='leftouter', matrix1_postfix='_m1', matrix2_postfix='_m2', use_mask=False, progress_message=True)`

`remotior_sensus.core.table_manager.join_tables(table1, table2, field1_name, field2_name, postfix='2', nodata_value=None, join_type='left', n_processes: int | None = None, progress_message=True, min_progress=None, max_progress=None)`

`remotior_sensus.core.table_manager.matrix_to_csv(matrix, output_path, fields=None, field_decimals: int | list = 2, separator=None, decimal_separator=None, nodata_value=None, nodata_value_output='nan', progress_message=True)`

#### Parameters

- **matrix** – input matrix
- **output\_path** – output path
- **fields** – optional list of fields to export
- **field\_decimals** – integer number of decimals for decimal fields or list of integer values for decimal fields
- **separator** – separator of fields
- **decimal\_separator** – optional decimal separator for float values replacing . character
- **nodata\_value** – optional nodata value to be replaced
- **nodata\_value\_output** – optional string to replace nodata value in output
- **progress\_message**

`remotior_sensus.core.table_manager.open_file(file_path: str, separators: str | list | None = None, field_names: list | None = None, skip_first_line: bool | None = True, progress_message: bool | None = True) → recarray`

Opens a file.

Opens a file by reading the content and creating a table (which is a NumPy structured array). File formats csv and dbf are supported.

#### Parameters

- **file\_path** – path of output file.
- **separators** – list of characters used as separator in csv files; default is tab and comma.
- **field\_names** – list of strings to be used as field names.
- **skip\_first\_line** – skip the first line in csv files, in case the first line contains field names.
- **progress\_message** – if True then start progress message; if False does not start the progress message (useful if launched from other tools).

#### Returns

Table as NumPy structured array.

#### Examples

##### Open a file

```
>>> table_1 = open_file('file.csv')
```

```
remotior_sensus.core.table_manager.pivot_matrix(matrix, row_field, column_function_list,
                                                secondary_row_field_list=None,
                                                filter_string=None, nodata_value=-999,
                                                cross_matrix=None, field_names=False,
                                                progress_message=True)
```

#### Parameters

- **matrix** – matrix array
- **row\_field** – field out\_column\_name of values used as rows
- **column\_function\_list** – list of lists of column out\_column\_name and function on values and optional out dtype
- **secondary\_row\_field\_list** – optional list of fields to be used as secondary rows
- **filter\_string** – optional string for filtering input matrix values
- **nodata\_value** – optional value for nodata
- **cross\_matrix** – optional, if True the output table field names are only combination values
- **field\_names** – optional, if True returns field names without performing the pivot matrix
- **progress\_message** – optional, if True display process message

```
remotior_sensus.core.table_manager.redefine_matrix_columns(matrix, input_field_names,
                                                         output_field_names=None,
                                                         progress_message=True)
```

#### Parameters

- **matrix** – matrix array
- **input\_field\_names** – list of field names to be included in output
- **output\_field\_names** – optional list of output field names with the same length as input\_field\_names

- **progress\_message** – optional, if True display process message

### Module contents

## 1.8 API Reference

### 1.8.1 remotior\_sensus package

#### Subpackages

#### Module contents

## 1.9 Changelog

### 1.9.1 v0.4.4

- Changed raster\_zonal\_stats to accept raster input as reference\_path
- Fixed handling nan value as nodata

### 1.9.2 v0.4.3

- First experimental implementation of Pytorch for band\_calc
- Minor fixes

### 1.9.3 v0.4.2

- Minor fixes

### 1.9.4 v0.4.1

- Fixed preprocessing calculation
- Minor fixes

### 1.9.5 v0.4.0

- Added tool “Band clustering” for unsupervised K-means classification of bandset
- Added tool “Raster edit” for direct editing of pixel values based on vector
- Added tool “Raster zonal stats” for calculating statistics of a raster intersecting a vector.
- Improved the NoData handling for multiprocessing calculation
- In “Band clip”, “Band dilation”, “Band erosion”, “Band sieve”, “Band neighbor”, “Band resample” added the option `multiple_resolution` to keep original resolution of individual rasters, or use the resolution of the first raster for all the bands
- In “Cross classification” fixed area based accuracy and added kappa hat metric
- In “Band combination” added option `no_raster_output` to avoid the creation of output raster, producing only the table of combinations
- In “Band calc” replaced nanpercentile with optimized calculation function
- Improved extraction of ROIs in “Band classification”
- Minor bug fixing and removed Requests dependency

### 1.9.6 v0.3.5

- Fixed Copernicus access token error
- Fixed automatic band wavelength definition in BandSet

### 1.9.7 v0.3.04

- Fixed Jupyter interface

### 1.9.8 v0.3.03

- Fixed Jupyter interface

### 1.9.9 v0.3.02

- Fixed Jupyter interface

### 1.9.10 v0.3.01

- Added functions for interactive interface in Jupyter environment
- Fixed Sentinel-2 band 8A identification in preprocess products

### 1.9.11 v0.2.01

- In Download Products added the functions to search and download Collections from Microsoft Planetary Computer: Sentinel-2, Landsat, ASTER, MODIS Surface Reflectance 8-Day, and Copernicus DEM

### 1.9.12 v0.1.24

- Fixed band calc calculation with multiband raster as bandset
- Fixed preview path for Copernicus products

### 1.9.13 v0.1.23

- Minor fixes

### 1.9.14 v0.1.22

- Fixed prepare input function
- Fixed logger for multiprocessing

### 1.9.15 v0.1.21

- Fixed requirements

### 1.9.16 v0.1.20

- Fixed Copernicus search and download service

### 1.9.17 v0.1.19

- Fixed Copernicus search and download service

### 1.9.18 v0.1.18

- Added Copernicus download service from <https://catalogue.dataspace.copernicus.eu> if copernicus\_user and copernicus\_password are provided.

### 1.9.19 v0.1.17

- Fixed spectral signature calculation for multiband raster
- Fixed closing multiprocessing at exit

### 1.9.20 v0.1.16

- Fixed issue in block size calculation for multiprocessing in case of large input raster and low RAM;
- Fixed management of bandsets using multiband rasters;
- Minor fixes to multiprocessing download;
